

Captchas & The Net

And We Call It "Machine Learning"

Bug Of The Day...

- Yet Another Buffer overflow...
- You think we'd be bored of them by now
- But...
- The operating system and device drivers are special...
- They need very low level access
- As they are working in a world where everything *is* just a big pile of bits!
- Perhaps you could use rust...
- But you would need to rewrite a huge amount of code

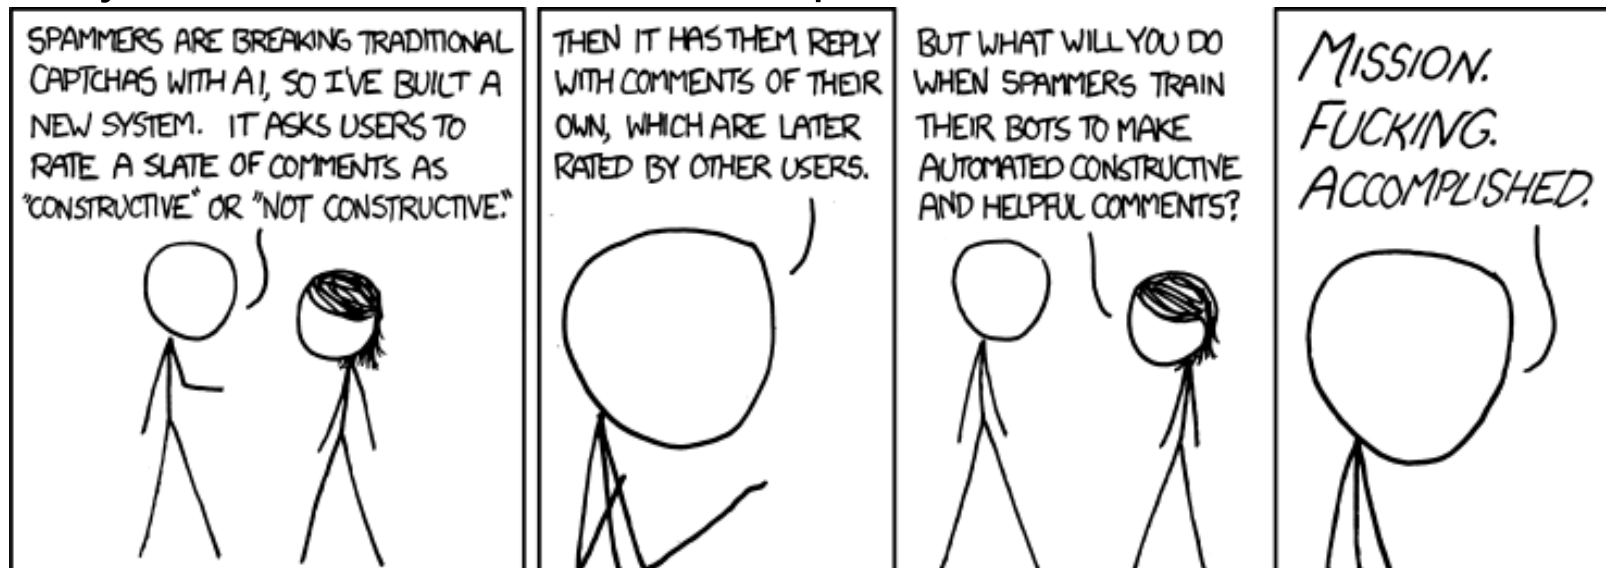

The screenshot shows an Ars Technica article. At the top, the Ars Technica logo is visible. Below it, a green line indicates a 'NOTICE OF ABSENCE'. The main headline reads 'Unpatched Linux bug may open devices to serious attacks over Wi-Fi'. A sub-headline states 'Buffer overflow can be triggered in Realtek Wi-Fi chips, no user interaction needed.' The author is identified as 'DAN GOODIN' and the date is '10/17/2019, 2:35 PM'.

The Problem: Automation...

- You host some website...
- It is intended for *human* usage
 - One person, one mouse, one clickstream of behavior...
- But you want to lock out *robot* usage
- Why?
 - Selling something
 - Offering something for free
 - Dealing with load from an attack
- Enter the CAPTCHA:
A way to go “Is this a human?”

CAPTCHAs: How Lazy Cryptographers Do AI

- The whole point of CAPCHAs is **not** just to solve "is this human"...
- But leverage bad guys to force them to solve hard problems
- Primarily focused on machine vision problems

CAPTCHAs

- *Reverse Turing Test*: present “user” a challenge that’s easy for a human to solve, hard for a program to solve
- One common approach: distorted text that’s difficult for character-recognition algorithms to decipher

Qualifying question

Just to prove you are a human, please answer the following math challenge.

Q: Calculate:

$$\frac{\partial}{\partial x} \left[4 \cdot \sin \left(7 \cdot x - \frac{\pi}{2} \right) \right] \Big|_{x=0}$$

A:

mandatory

Note: If you do not know the answer to this question, reload the page and you'll get another question.

Issues with CAPTCHAs

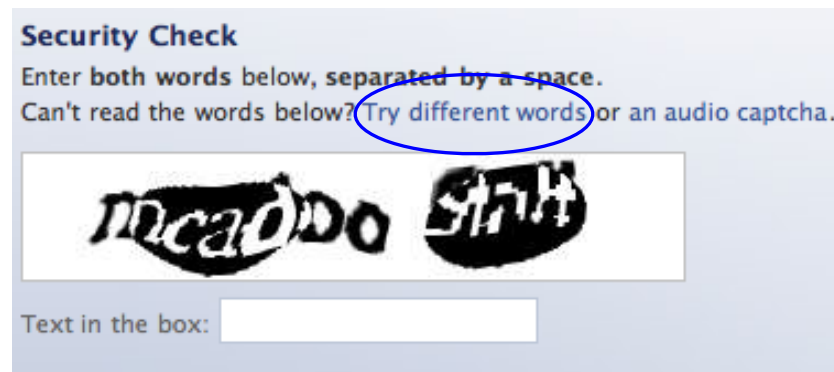

- Inevitable arms race: as solving algorithms get better, defense erodes

Figure 4: Examples of images from the hard CAPTCHA puzzles dataset.

Issues with CAPTCHAs

- Inevitable arms race: as solving algorithms get better, defense erodes, or gets harder for humans

Asirra

Asirra is a human interactive proof that asks users to identify photos of cats and dogs. It's powered by over **two million photos** from our unique partnership with Petfinder.com. Protect your web site with Asirra — free!

Please click on the images that show cats:

ANTI CAPTCHA SOLVING SERVICE

- ✓ **Cheapest price on the market**
Starting from 0.5USD per 1000 images, depending on your daily upload volume
- ✓ **Pay as you go**
Pay-per-captcha payment basis. Minimum refill is 1 USD, no recurring charges
- ✓ **99.99% uptime since 2007**
Vast amount of workers and premium infrastructure allows us to provide highly reliable 24/7/365 service
- ✓ **Solving Google Recaptcha since 2016**
You may fully rely on our stable solution and forget about browser emulation

API

Documentation in English

Created by Administrator
Last updated Oct 17, 2018

About version 2.0

API version 2 works on address <https://api.anti-captcha.com/> and it works only via HTTP methods, data format is JSON.

To solve a captcha, you need:

1. Create captcha task via via `createTask` method which will return task ID.
2. Wait a few seconds to let system assign captcha to an employee and retrieve result
3. Request captcha solution with `getTaskResult` method. If captchas is not solved yet wait step #2.

```

graph LR
    A["createTask  
- NoCaptchaTask  
- NoCaptchaTaskProxyless  
- ImageToTextTask"] -- "...wait 5-10s..." --> B["getTaskResult"]
  
```

Re: CAPTCHAs – Understanding CAPTCHA-Solving Services in an Economic Context

Marti Motoyama, Kirill Levchenko, Chris Kanich, Damon McCoy,
Geoffrey M. Voelker and Stefan Savage

University of California, San Diego

{mmotoyam, klevchen, ckanich, dlmccoy, voelker, savage}@cs.ucsd.edu

Table 2: Percentage of responses from the services with correct answers for the language CAPTCHAs.

These Days: CAPTCHAs are ways of *training* AI systems

- Plus are all about an economic protection
- Even the best CAPTCHA doesn't say "Is this a human or a bot"...
- but...
- "Is this a human or a bot willing to spend a couple pennies?"
- Acts as a hard limit on what a CAPTCHA can really protect!

SO MUCH OF "AI" IS JUST FIGURING OUT WAYS TO OFFLOAD WORK ONTO RANDOM STRANGERS.

Network Security

- Why study network security?
 - Networking greatly extends our **overall attack surface**
 - Networking = the **Internet**
 - Opportunity to see *how large-scale design affects security issues*
 - Protocols a great example of *mindless agents* in action
- This lecture + next: sufficient background in networking to then explore security issues in next ~8 lectures
- Complex topic with many facets
 - We will omit concepts/details that aren't very security-relevant
 - But to no small extent we are speed running about 1/2 a dozen worth of "networking" lectures!
 - **By all means, ask questions when things are unclear**

Protocols

- A protocol is an **agreement on how to communicate**
- Includes **syntax** and **semantics**
 - How a communication is specified & structured
 - Format, order messages are sent and received
 - What a communication means
 - Actions taken when transmitting, receiving, or timer expires
- E.g.: making a comment in lecture?
 1. Raise your hand.
 2. Wait to be called on.
 3. Or: wait for speaker to **pause** and vocalize
 4. If unrecognized (after **timeout**): vocalize w/ “excuse me”

So Let's Do A Google Search...

- Walk into a coffee shop
- Open a laptop
- Search google...

Coffee Shop

Coffee Shop

1. Join the wireless network

Coffee Shop

1. Join the wireless network

Wireless access point(s)
continually shout:
**HEY, I'M WIRELESS
NETWORK Y, JOIN ME!**

Coffee Shop

1. Join the wireless network

If either match up, your laptop joins the network. Optionally performs a cryptographic exchange.

Coffee Shop

2. Configure your connection

Coffee Shop

2. Configure your connection

Coffee Shop

2. Configure your connection

192.168.1.14

The configuration includes:

- (1) An Internet address (**IP address**) your laptop should use; typ. 32 bits (IPv4). May also include 64b of the 128b IPv6 address
- (2) The address of a “**gateway**” system to use to access *hosts* beyond the local network
- (3) The address of a **DNS server** (“*resolver*”) to map names like `google.com` to IP addresses

Coffee Shop

3. Find the address of `google.com`

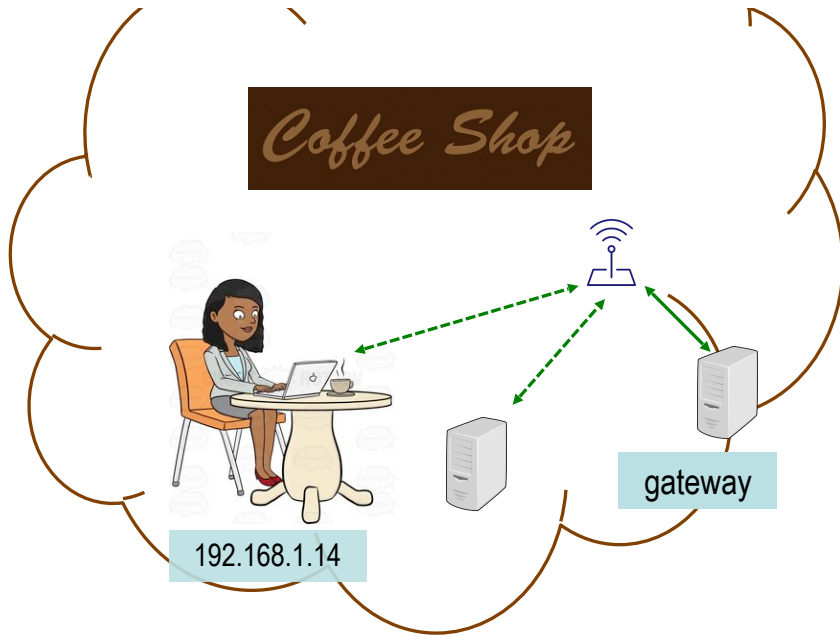

192.168.1.14

Your laptop sends a **DNS** request asking: “*address for google.com?*”

It's transmitted using the **UDP** protocol (lightweight, unreliable).

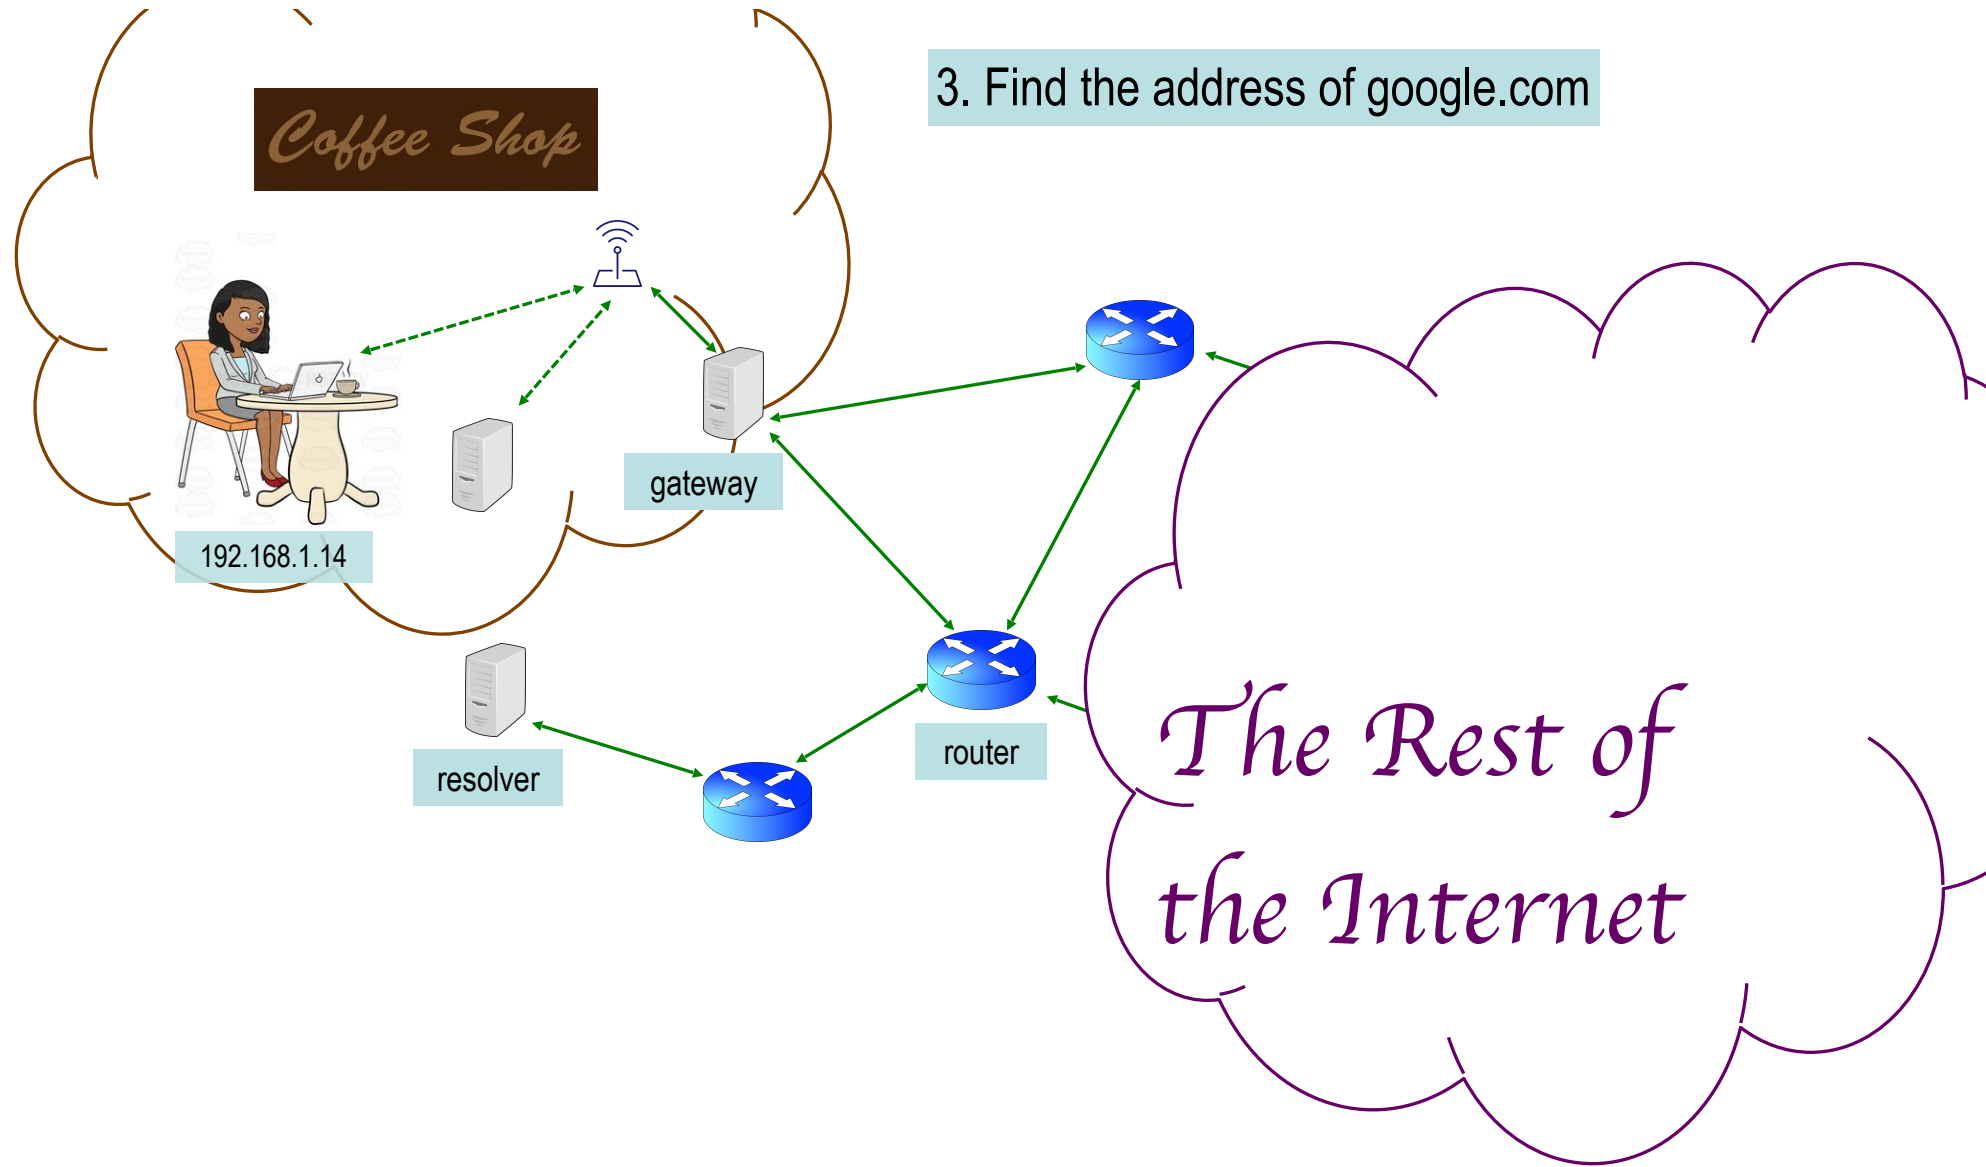

The DNS **resolver** might not be on the local network.

3. Find the address of google.com

3. Find the address of google.com

Coffee Shop

192.168.1.14

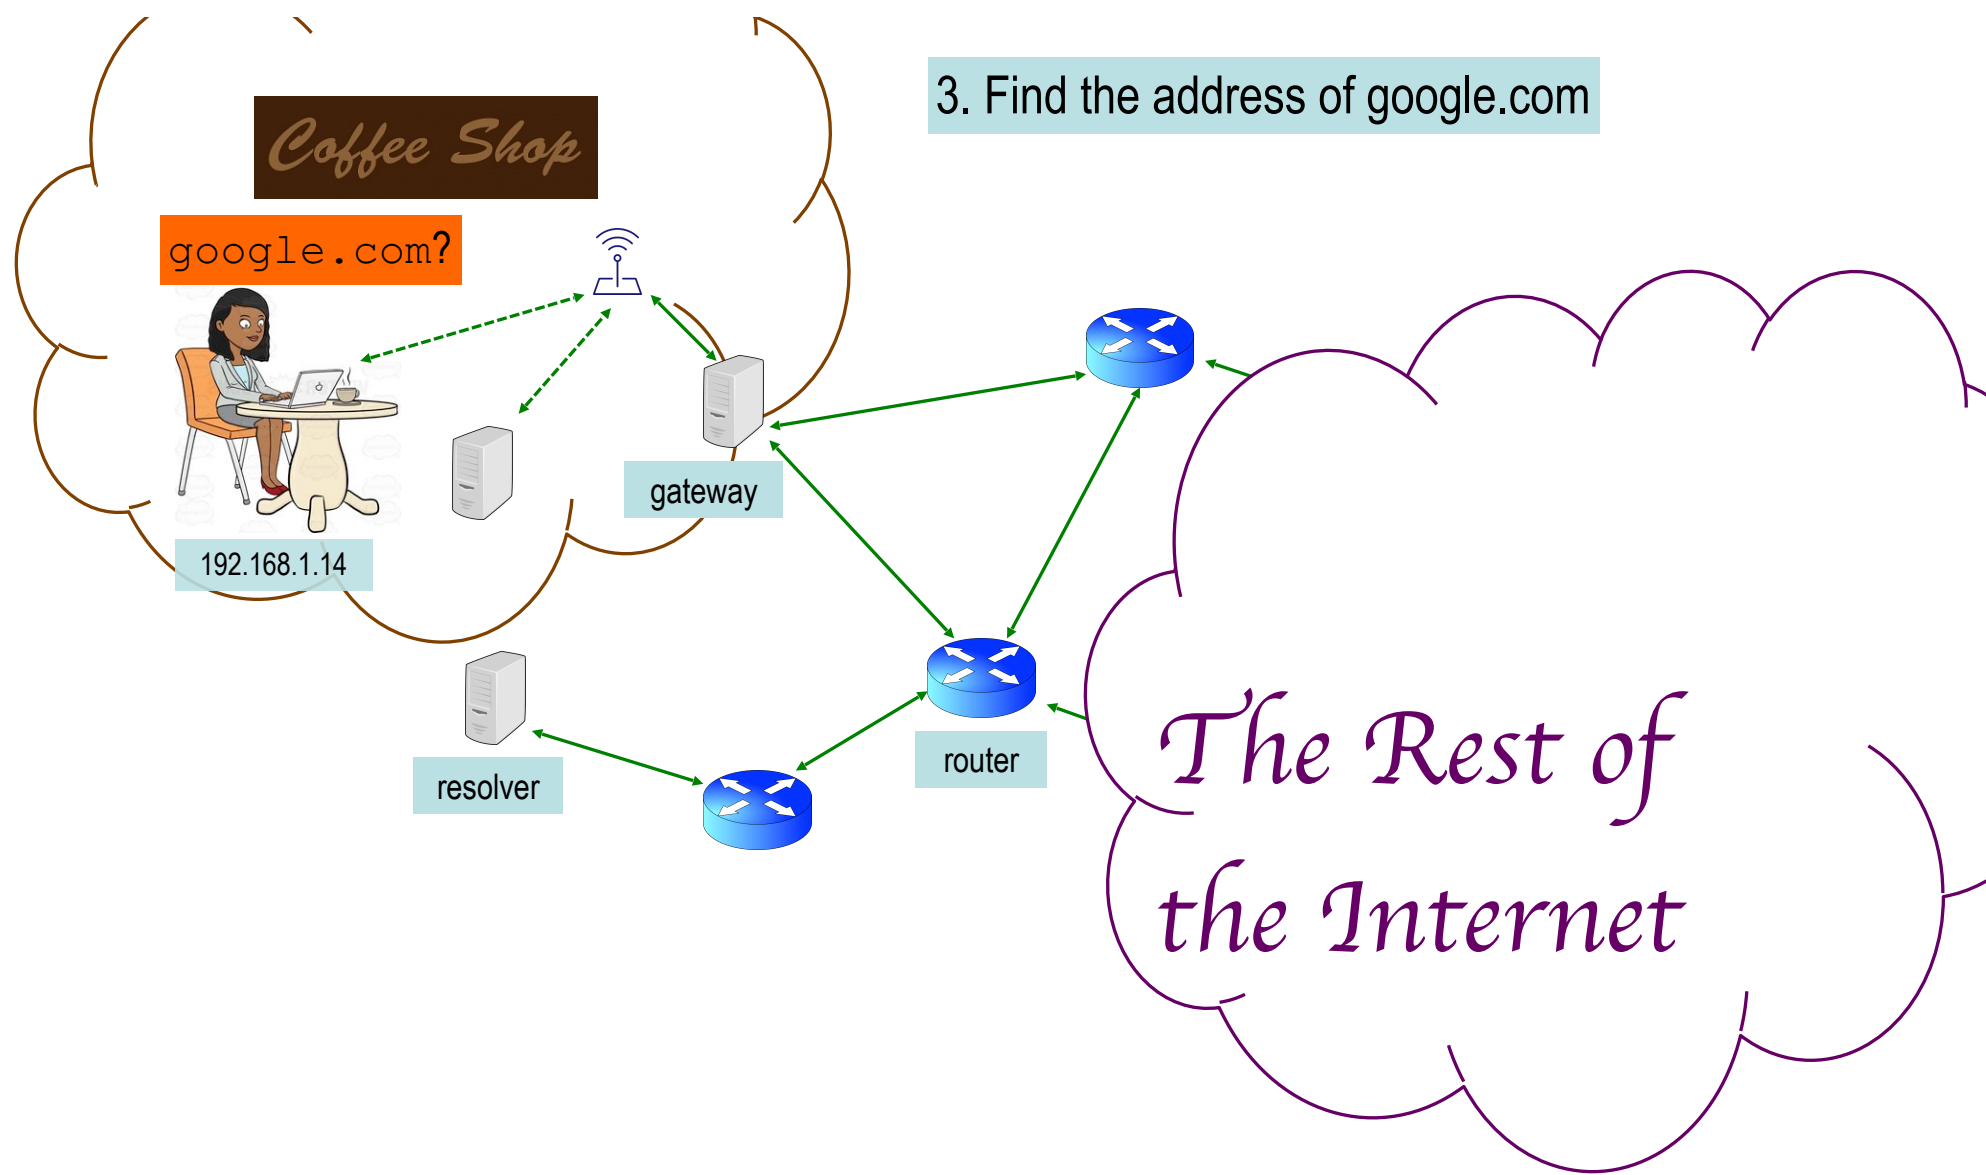

gateway

resolver

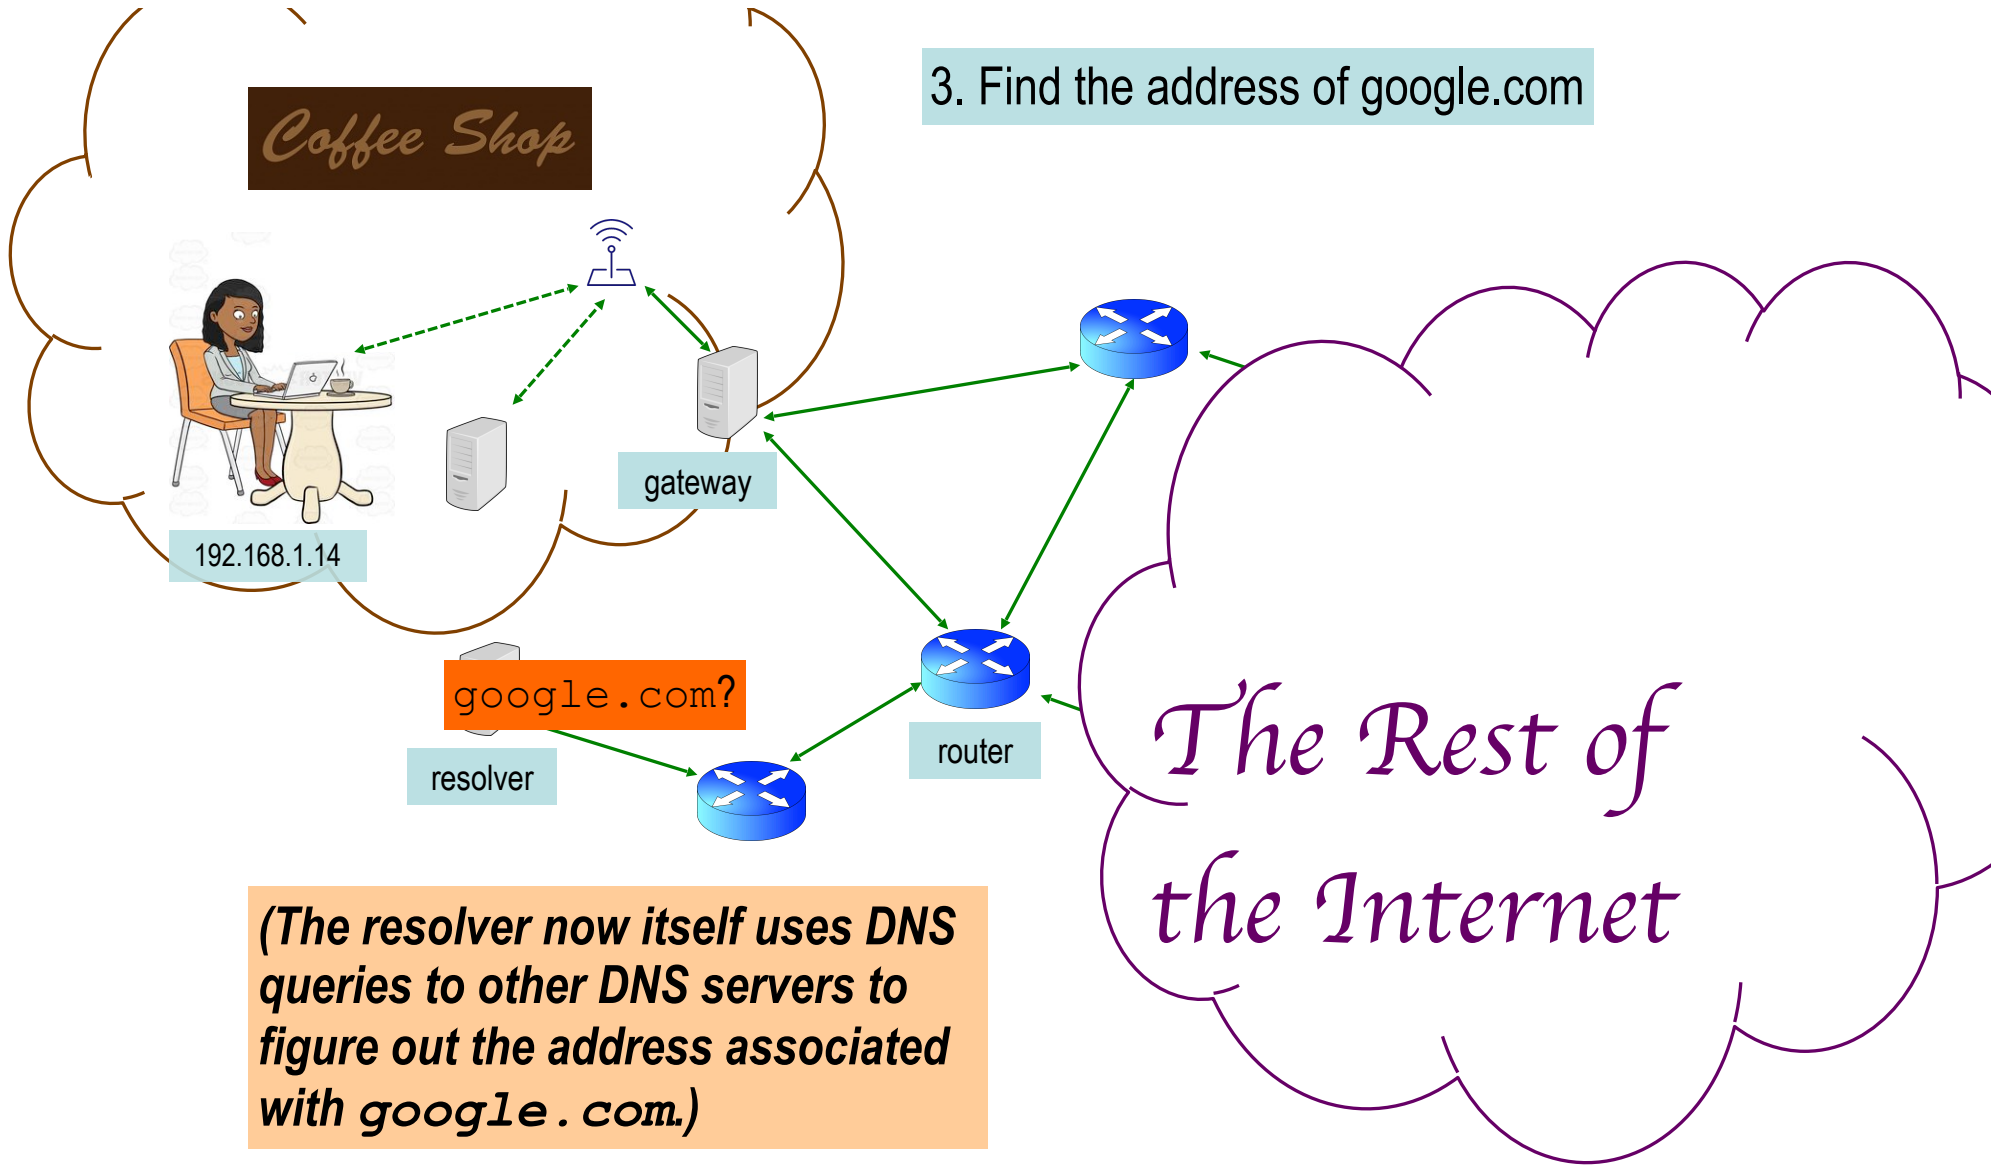

router

The Rest of the Internet

3. Find the address of google.com

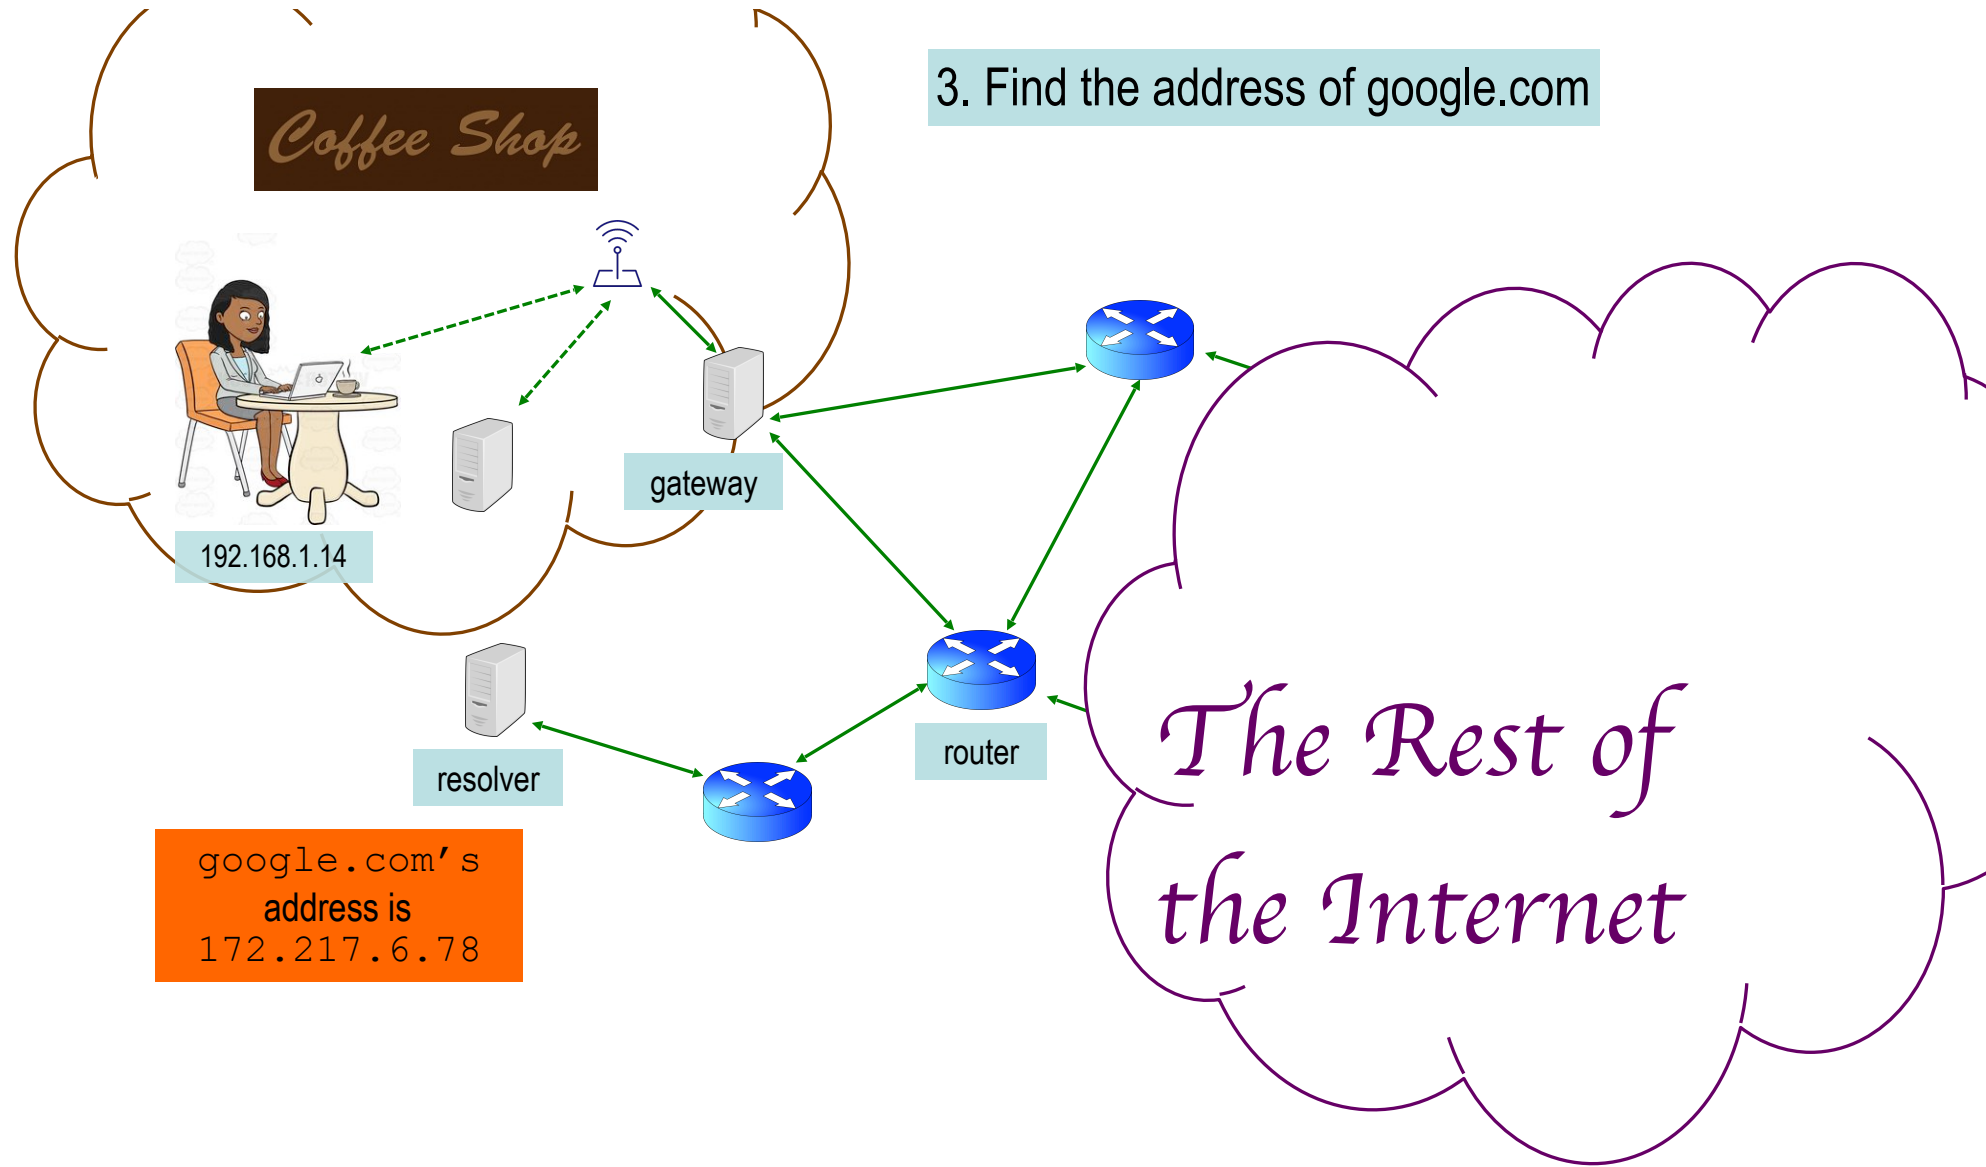

3. Find the address of google.com

(The resolver now itself uses DNS queries to other DNS servers to figure out the address associated with google.com.)

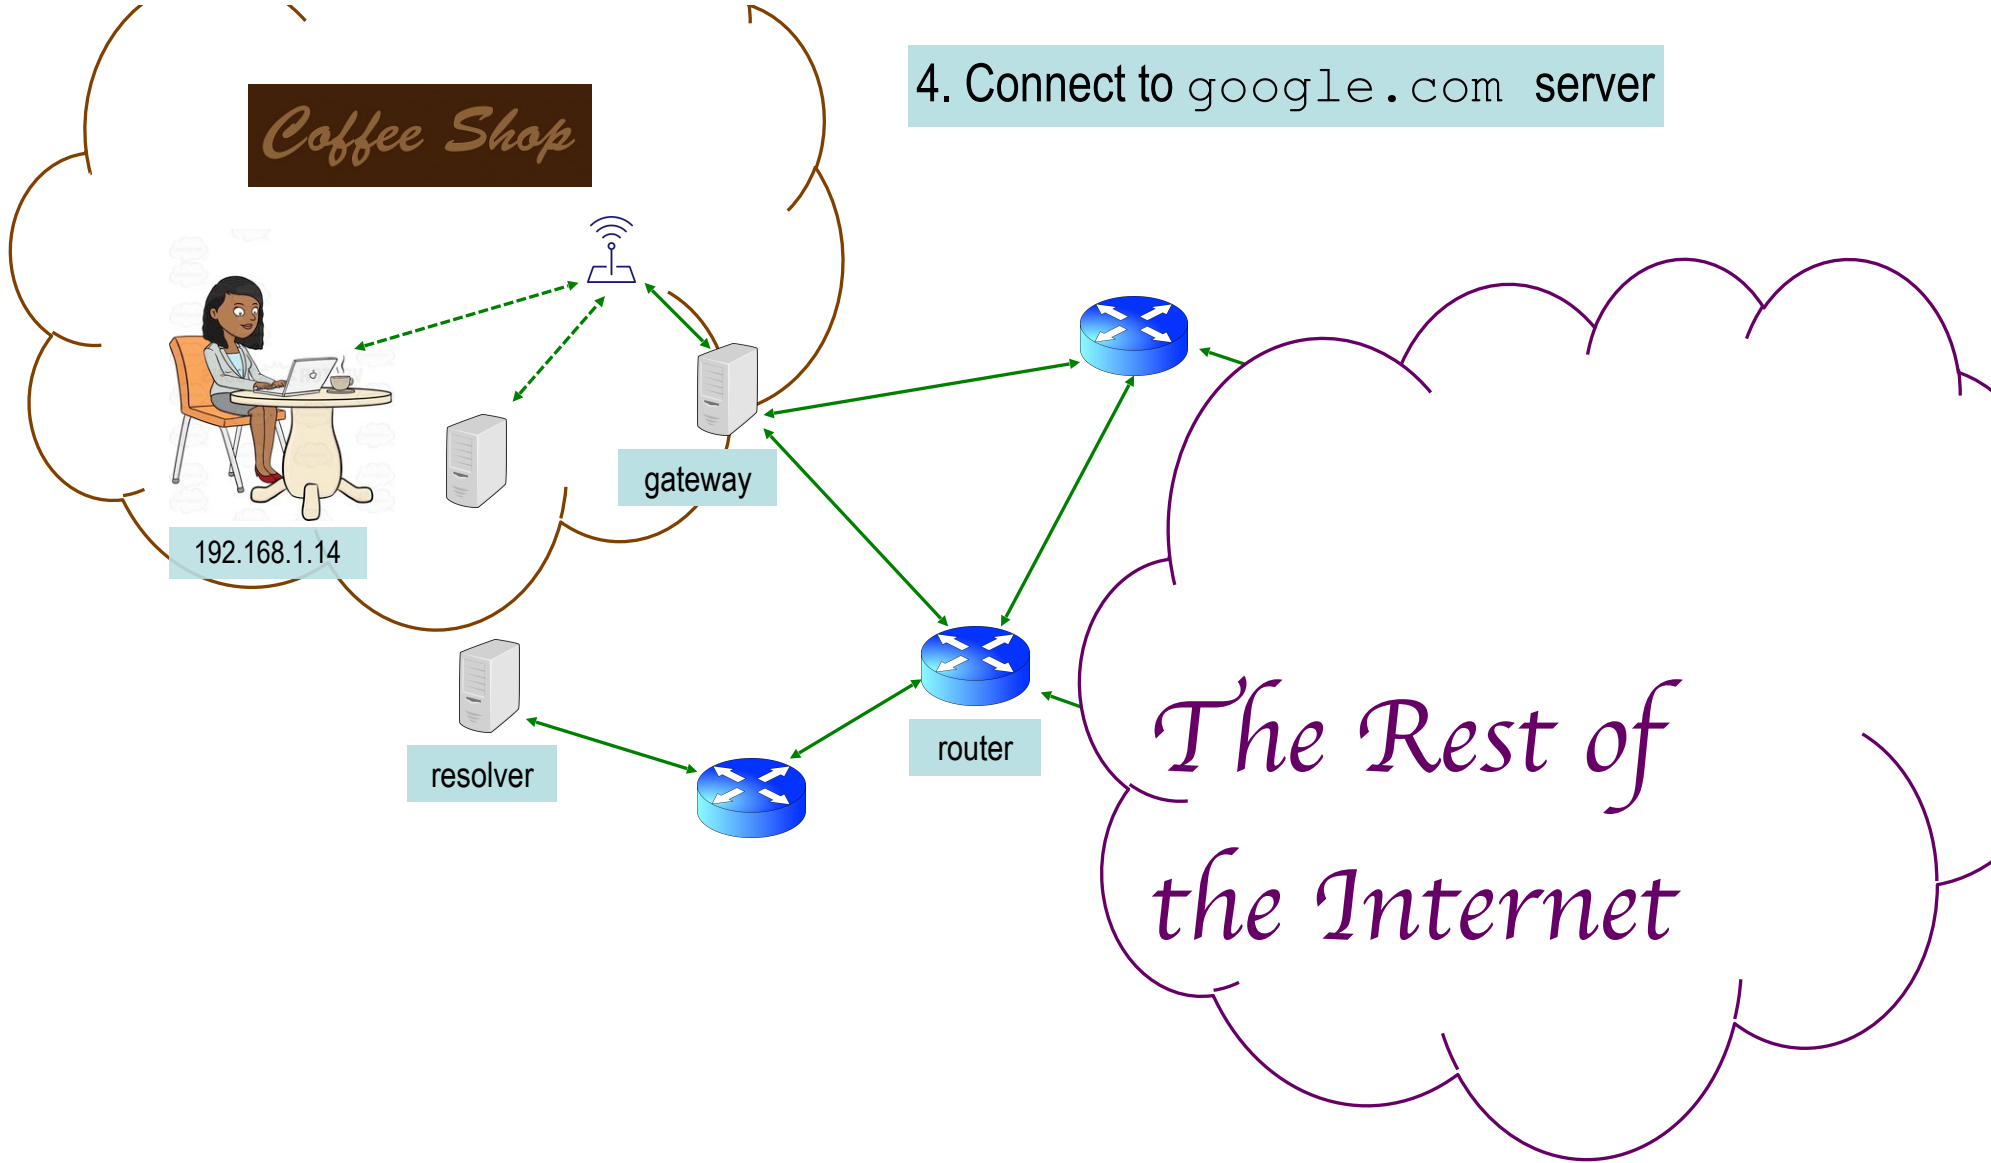

The Rest of the Internet

3. Find the address of google.com

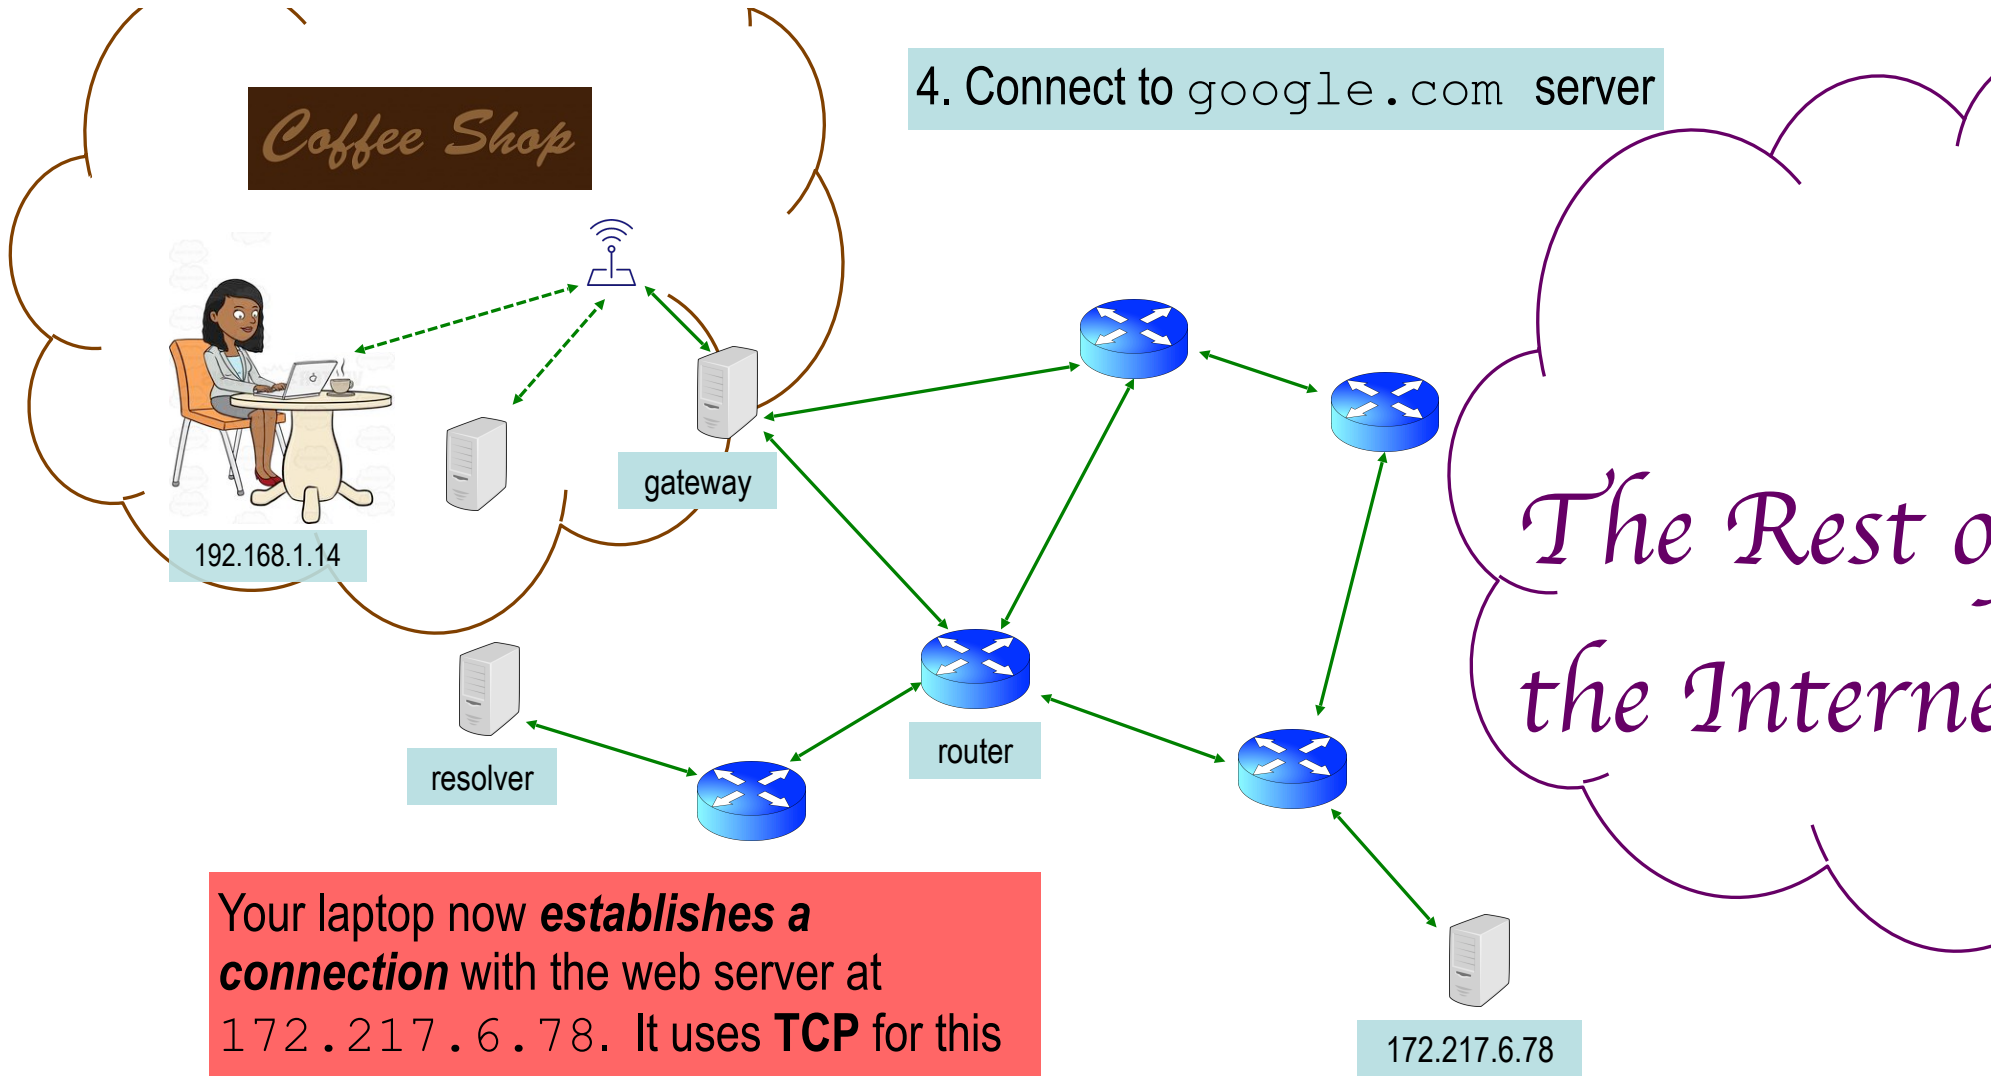

google.com's address is 172.217.6.78

4. Connect to google.com server

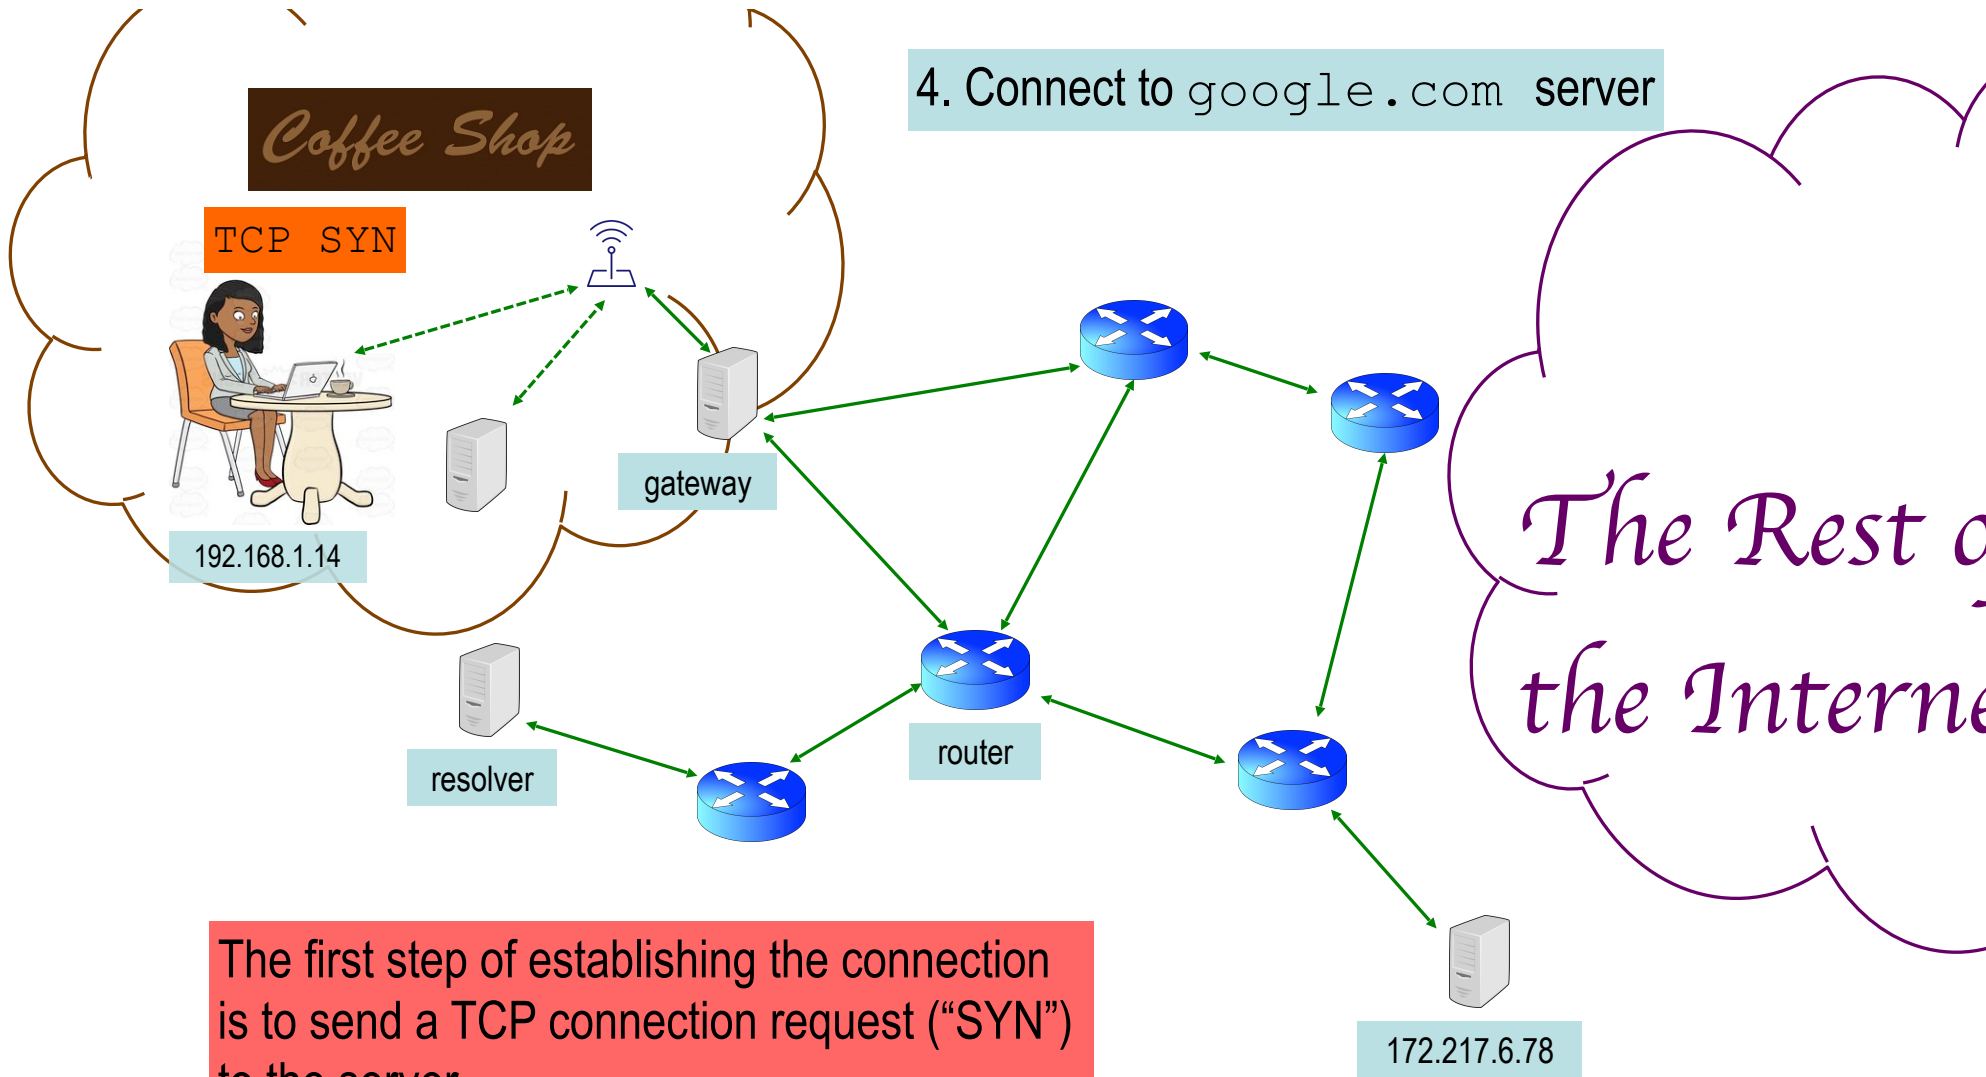

The Rest of the Internet

4. Connect to google.com server

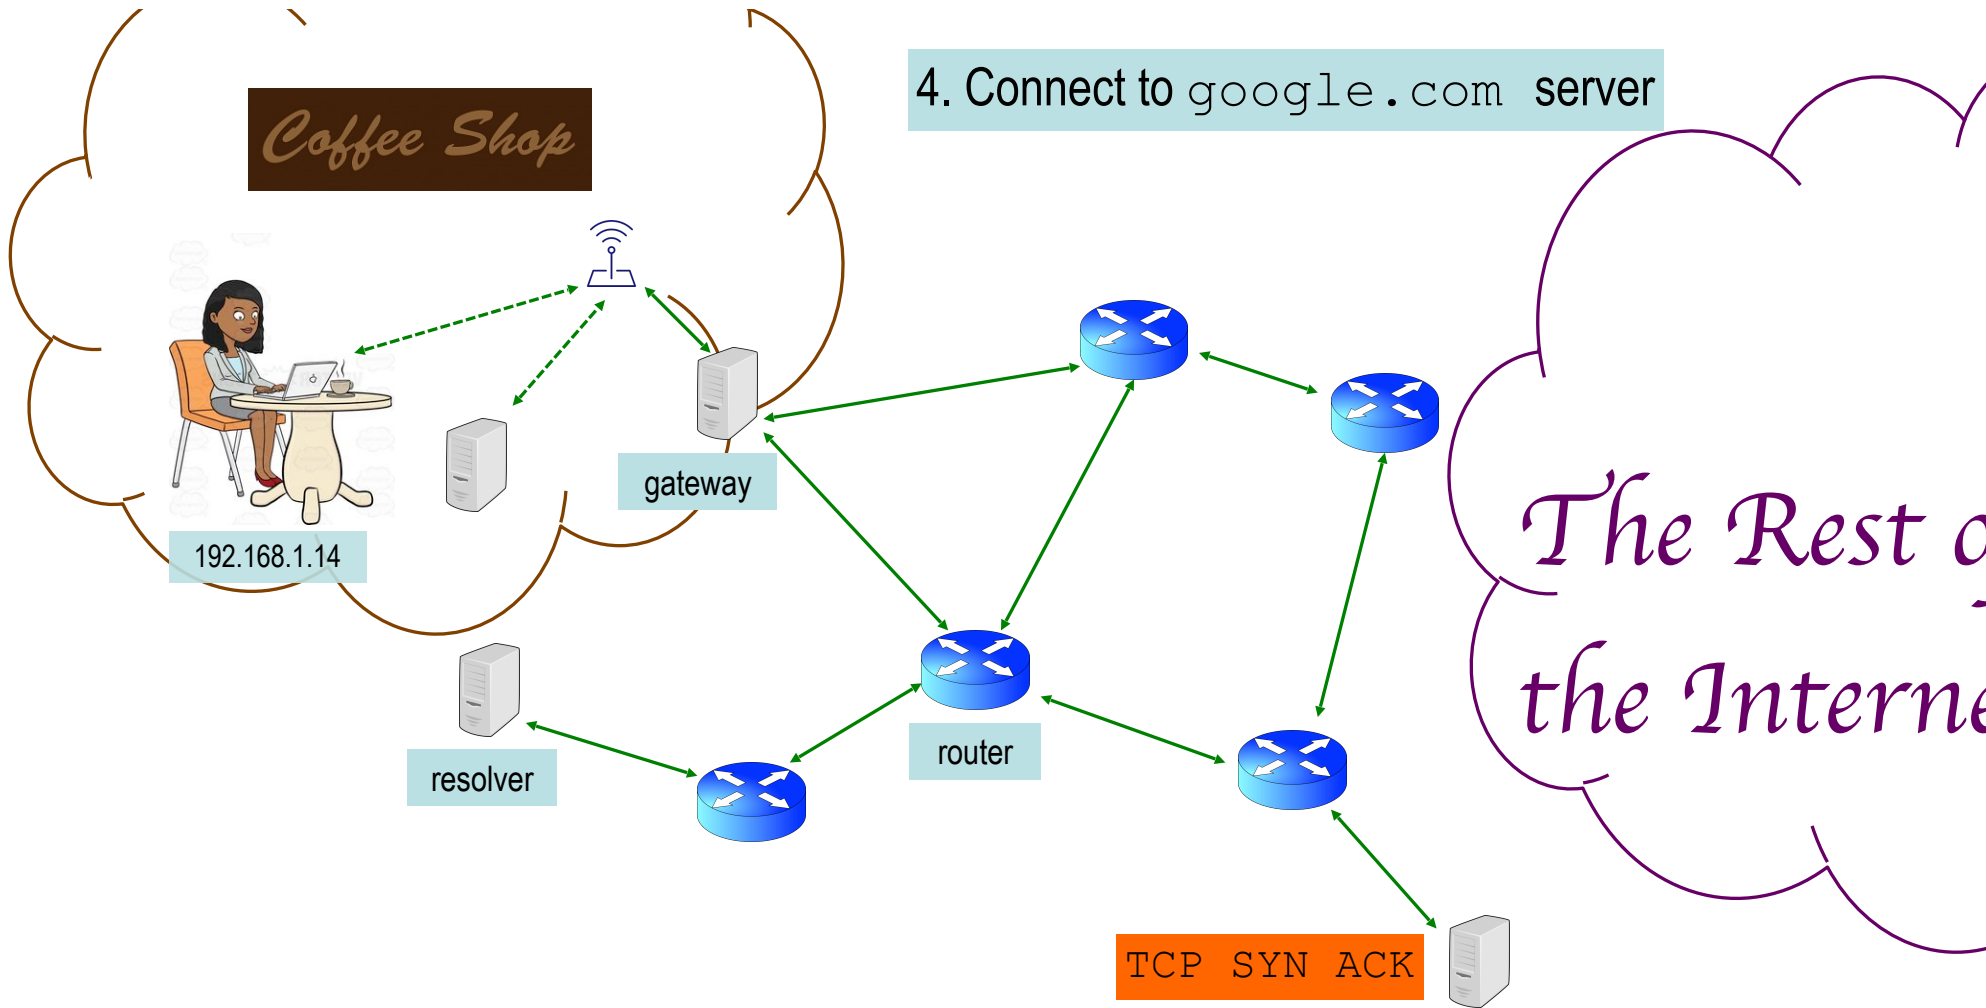

Your laptop now **establishes a connection** with the web server at 172.217.6.78. It uses **TCP** for this rather than UDP, to obtain reliability.

4. Connect to google.com server

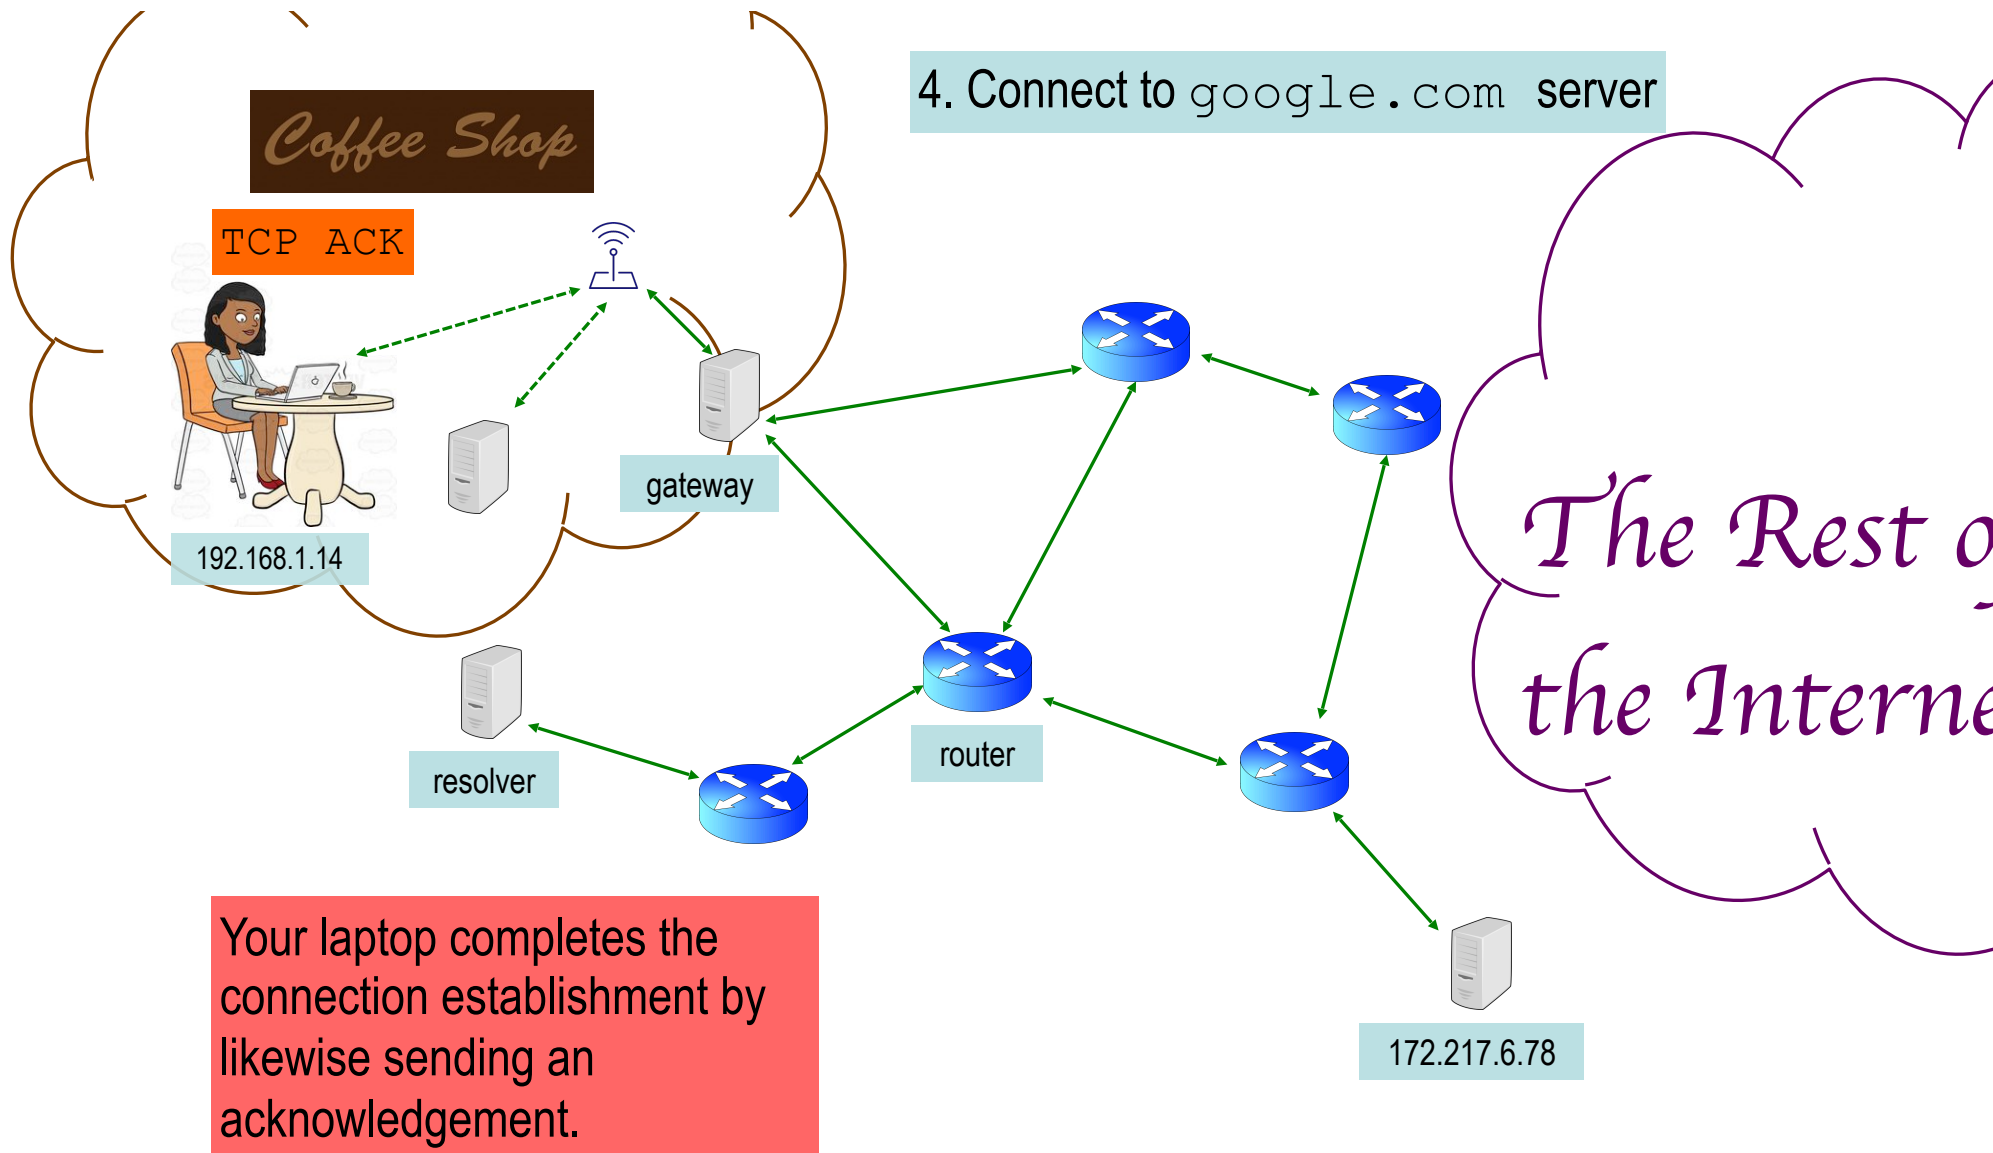

The first step of establishing the connection is to send a TCP connection request ("SYN") to the server.

4. Connect to google.com server

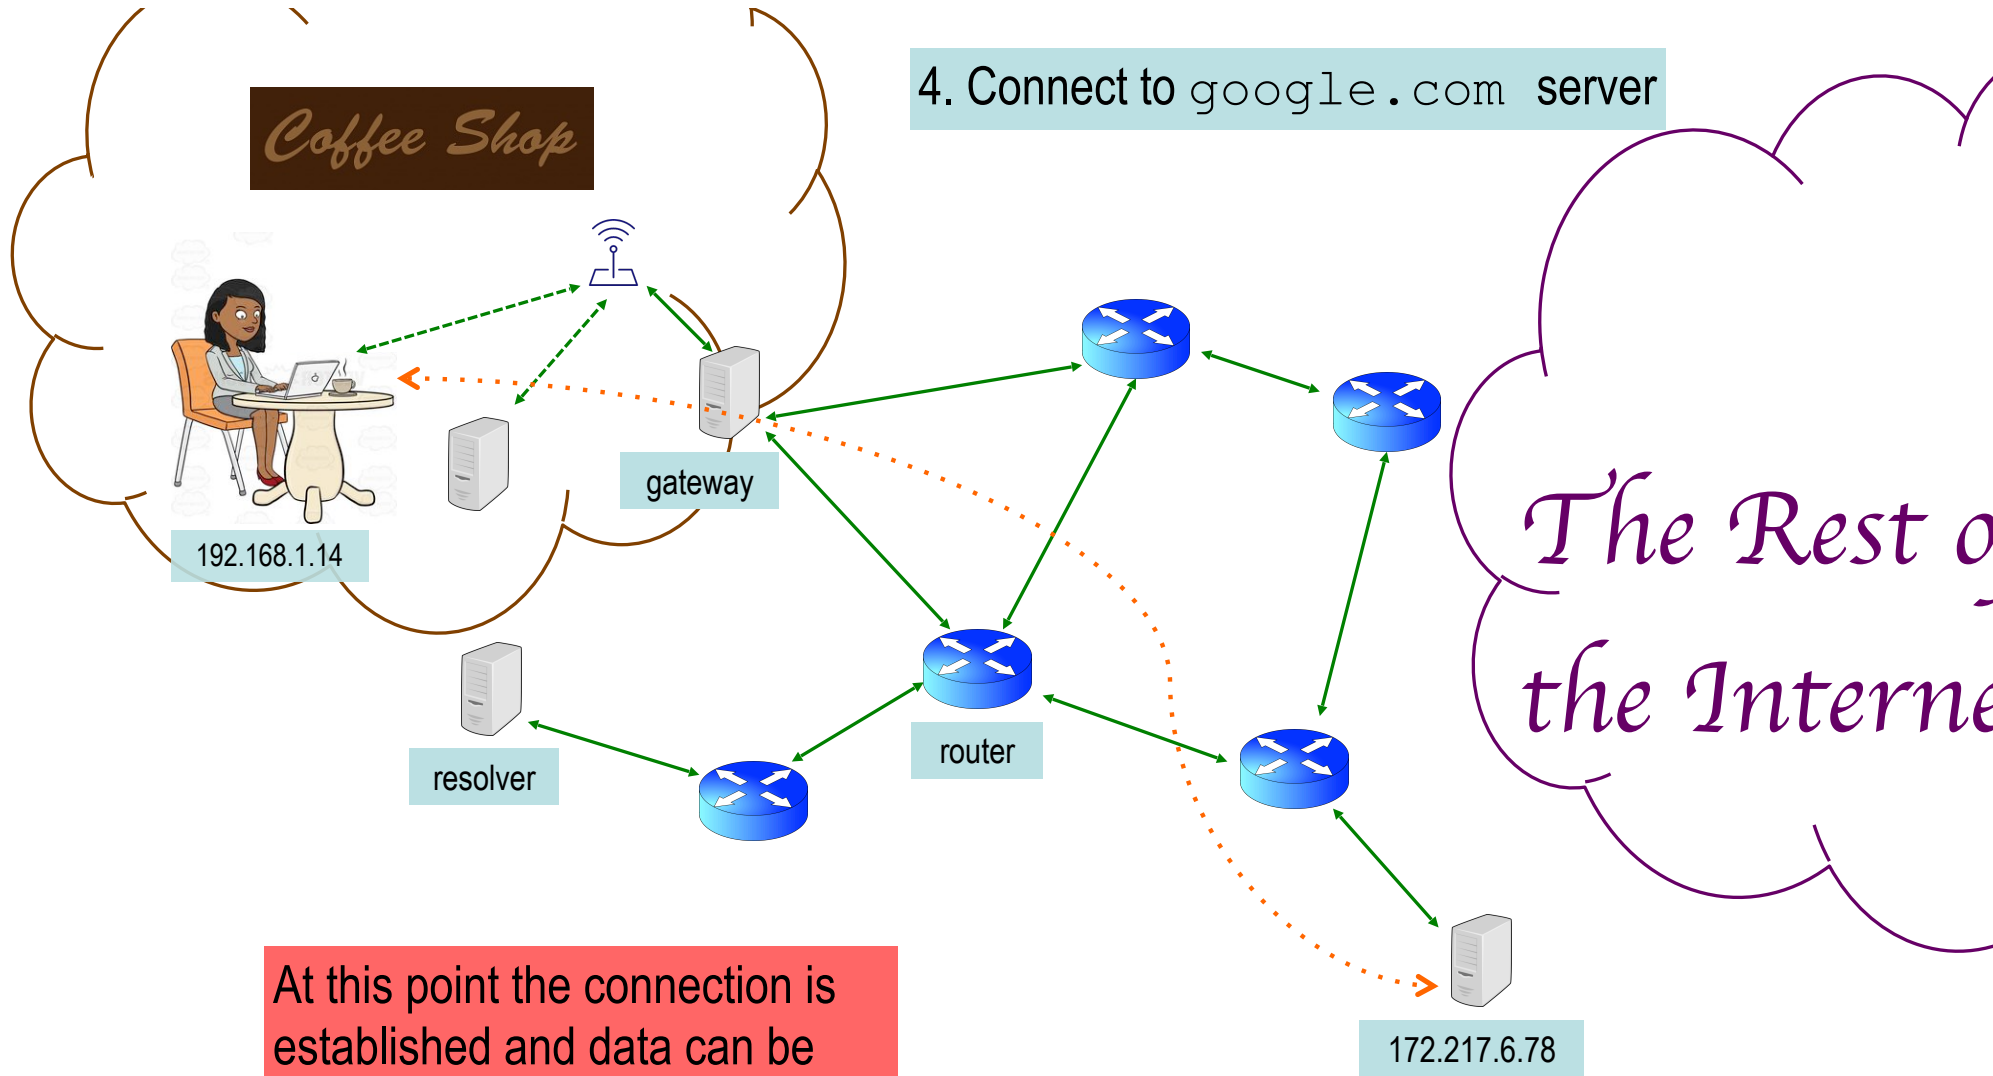

If the server accepts the connection, it replies with a "SYN ACK".

4. Connect to google.com server

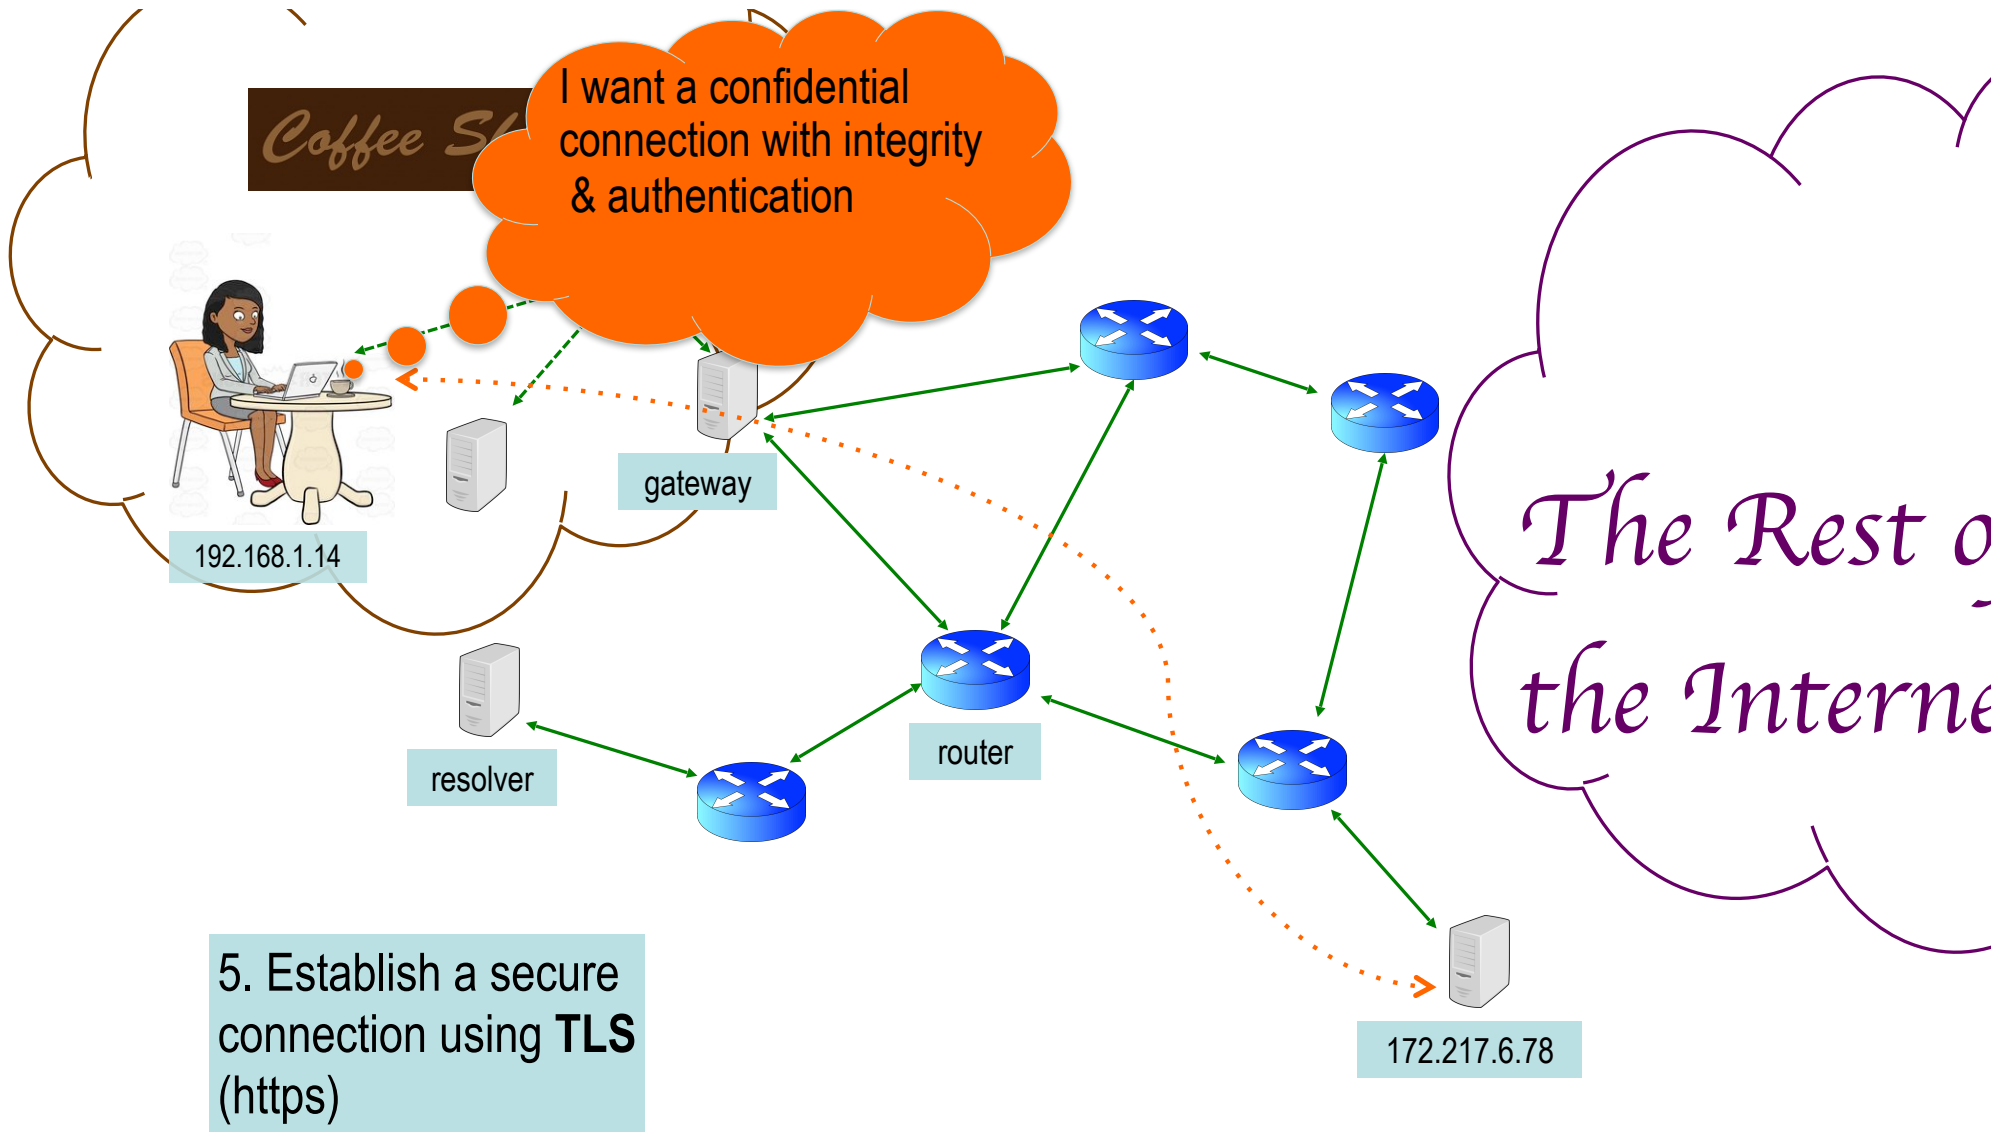

Your laptop completes the connection establishment by likewise sending an acknowledgement.

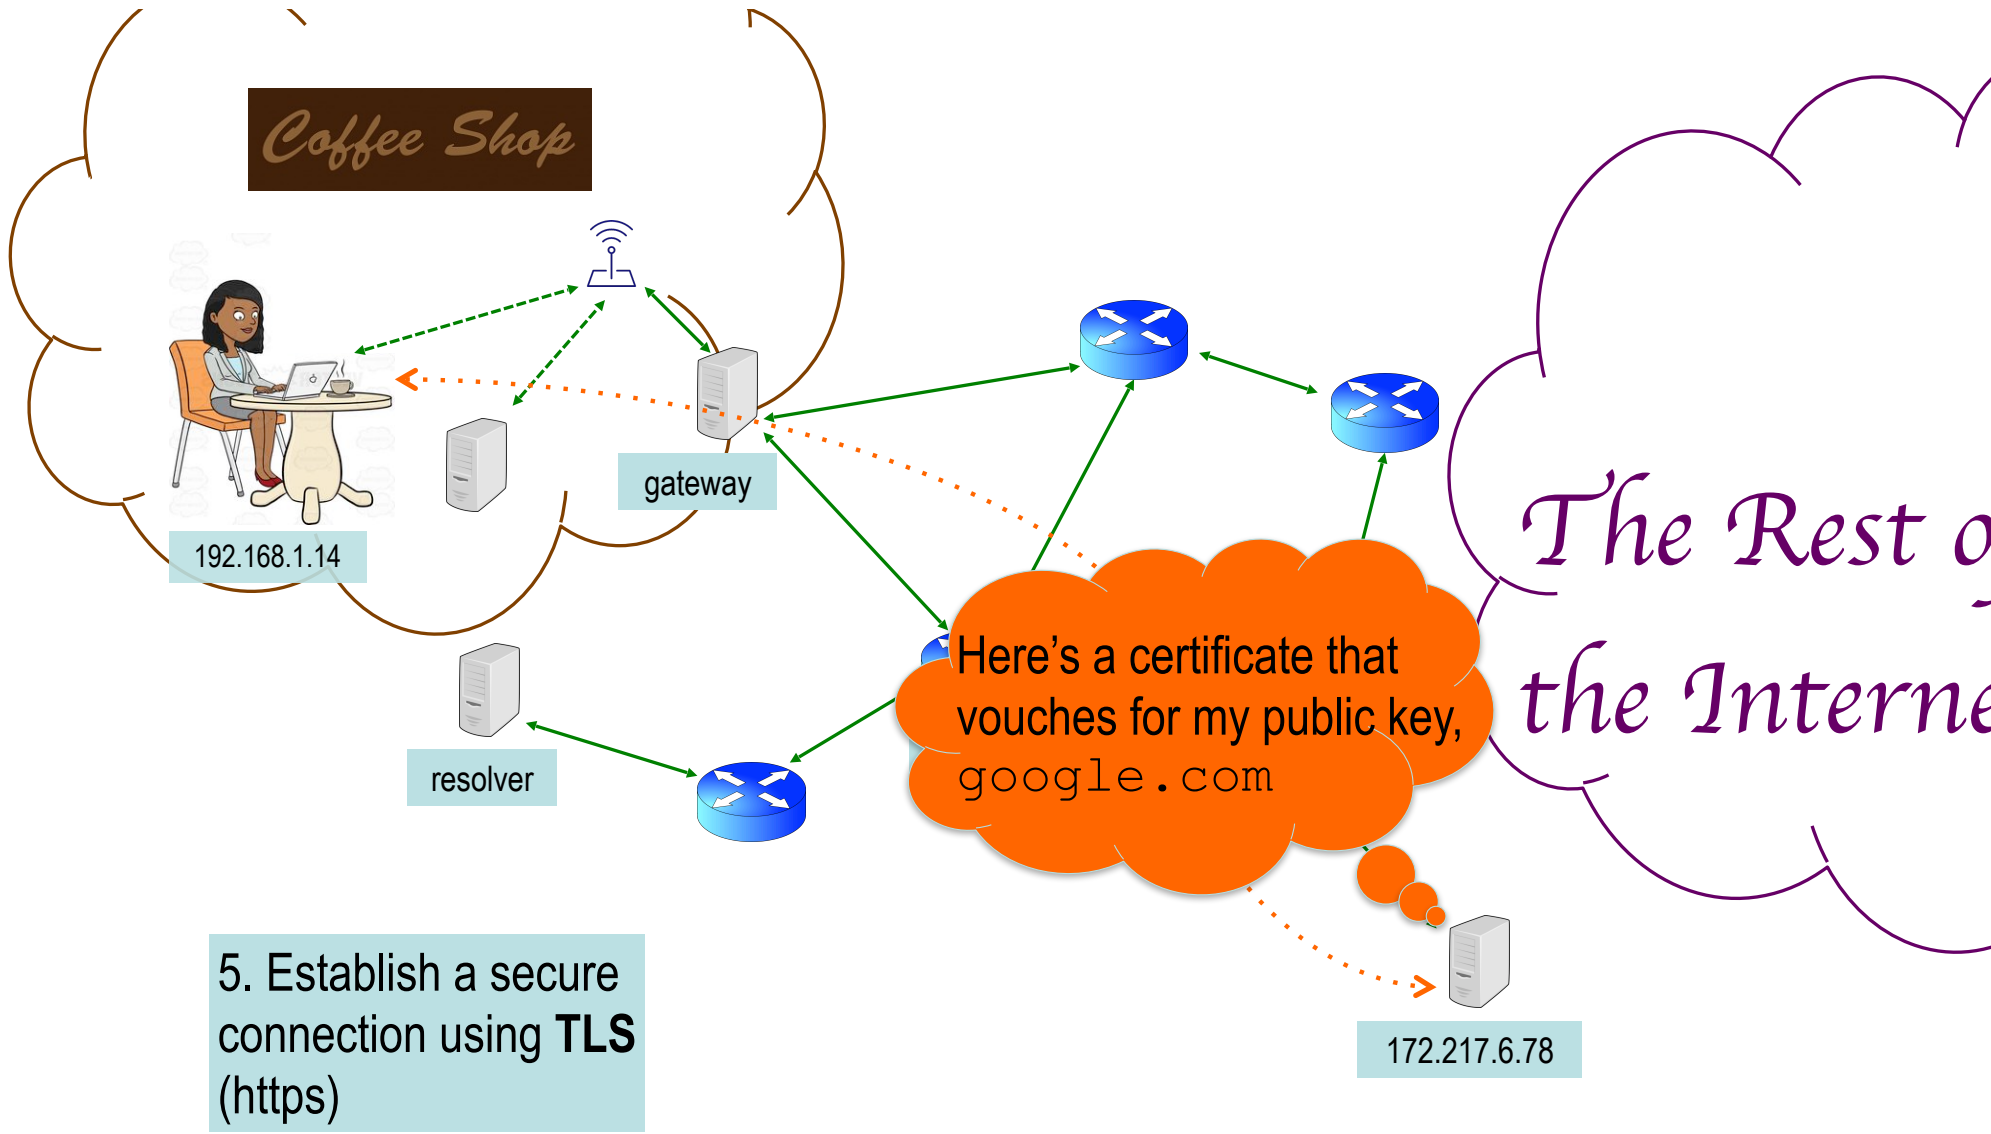

4. Connect to google.com server

At this point the connection is established and data can be (reliably) exchanged.

5. Establish a secure connection using **TLS** (https)

Coffee Shop

192.168.1.14

gateway

resolver

router

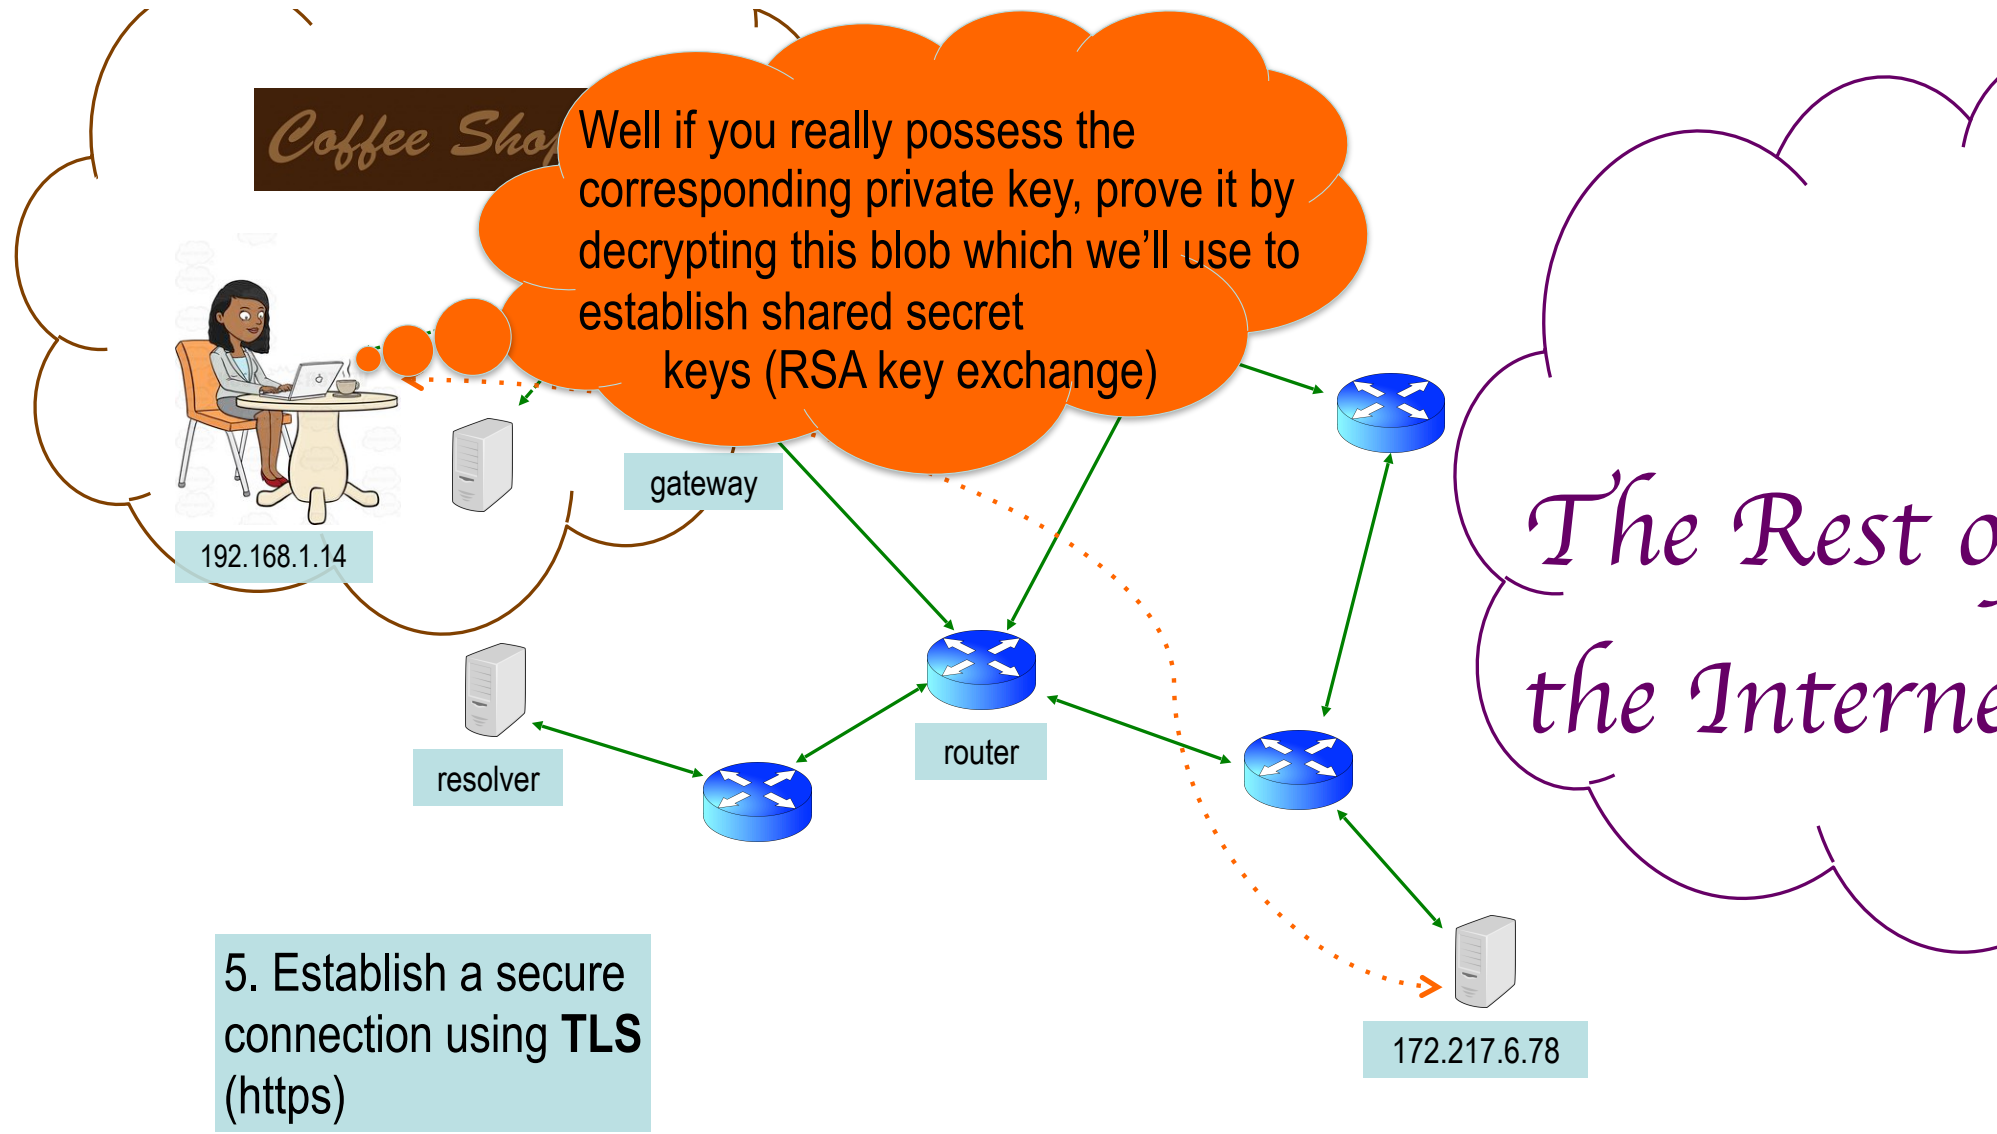

172.217.6.78

Well if you really possess the corresponding private key, prove it by decrypting this blob which we'll use to establish shared secret keys (RSA key exchange)

The Rest of the Internet

5. Establish a secure connection using **TLS** (https)

Coffee Shop

192.168.1.14

gateway

resolver

router

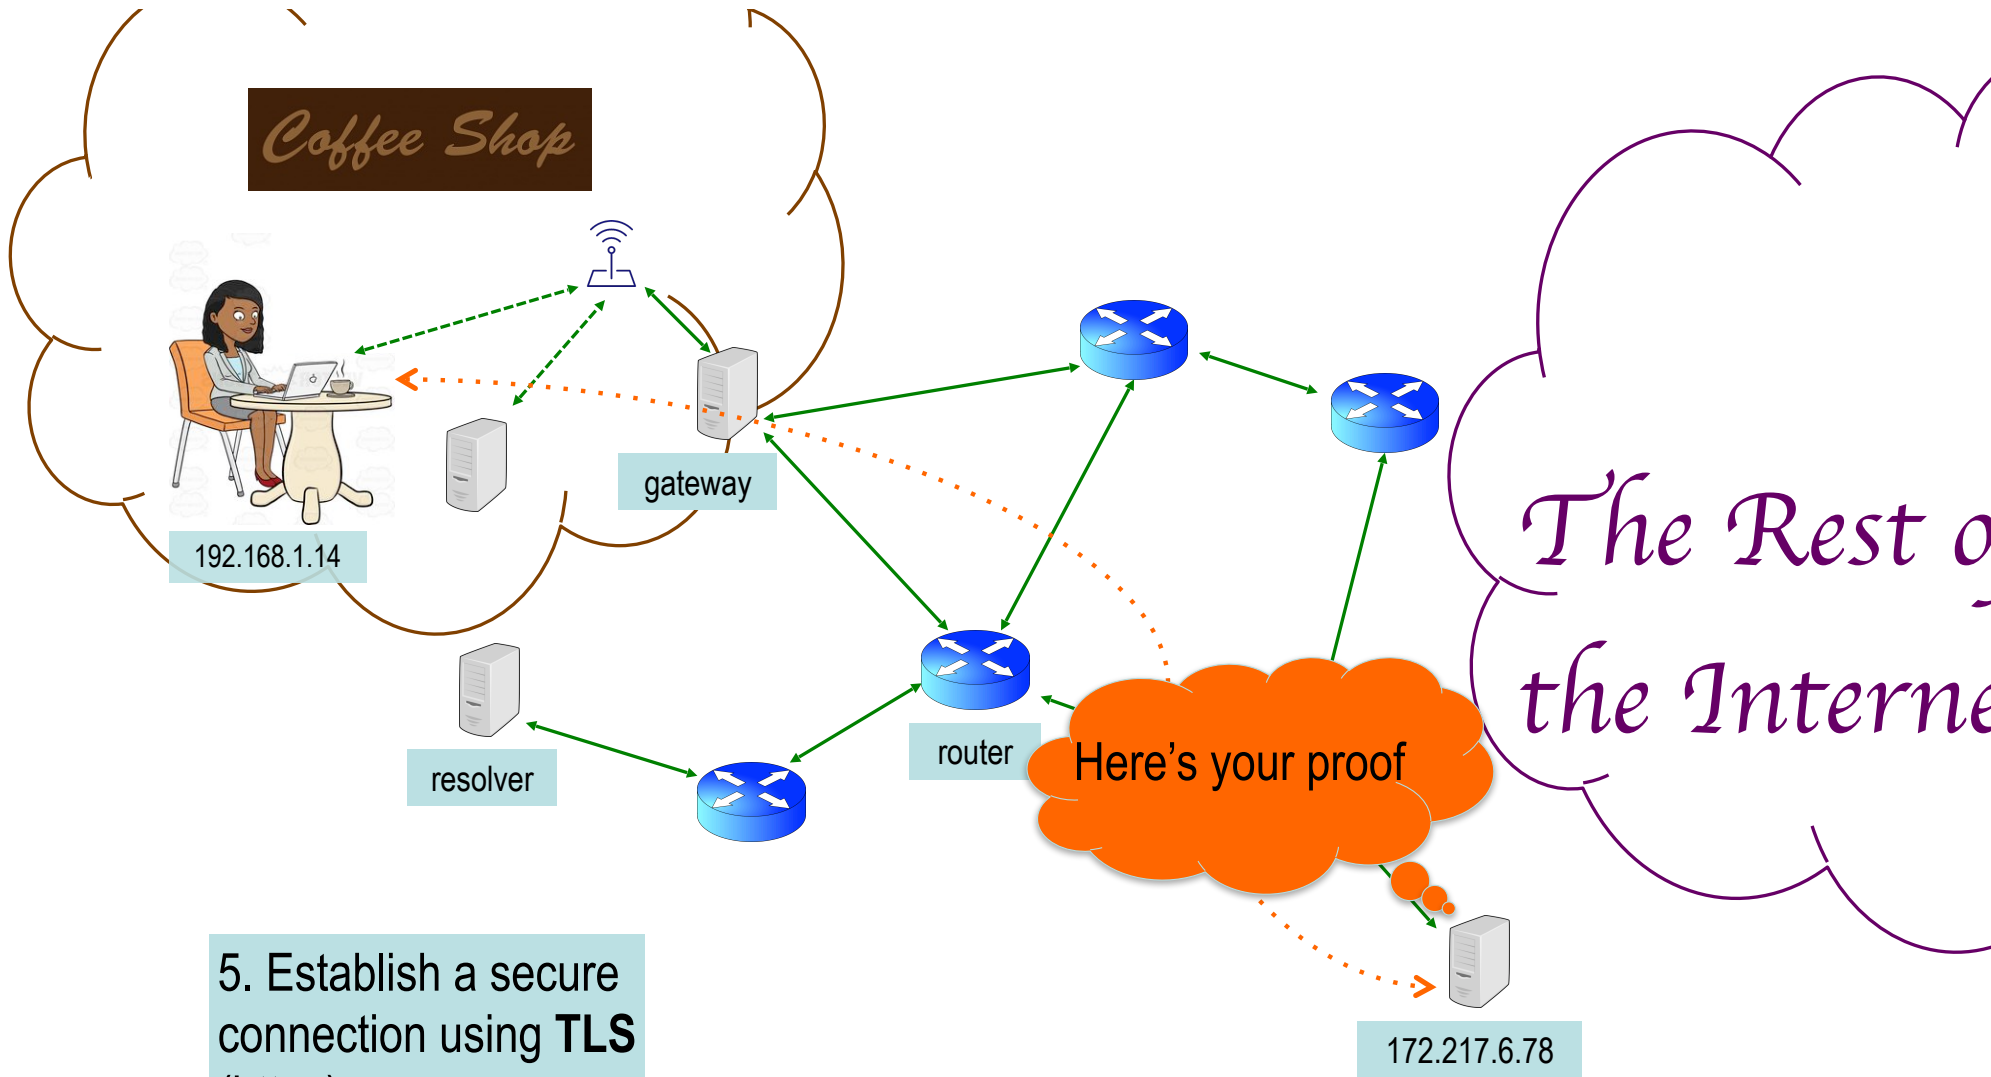

172.217.6.78

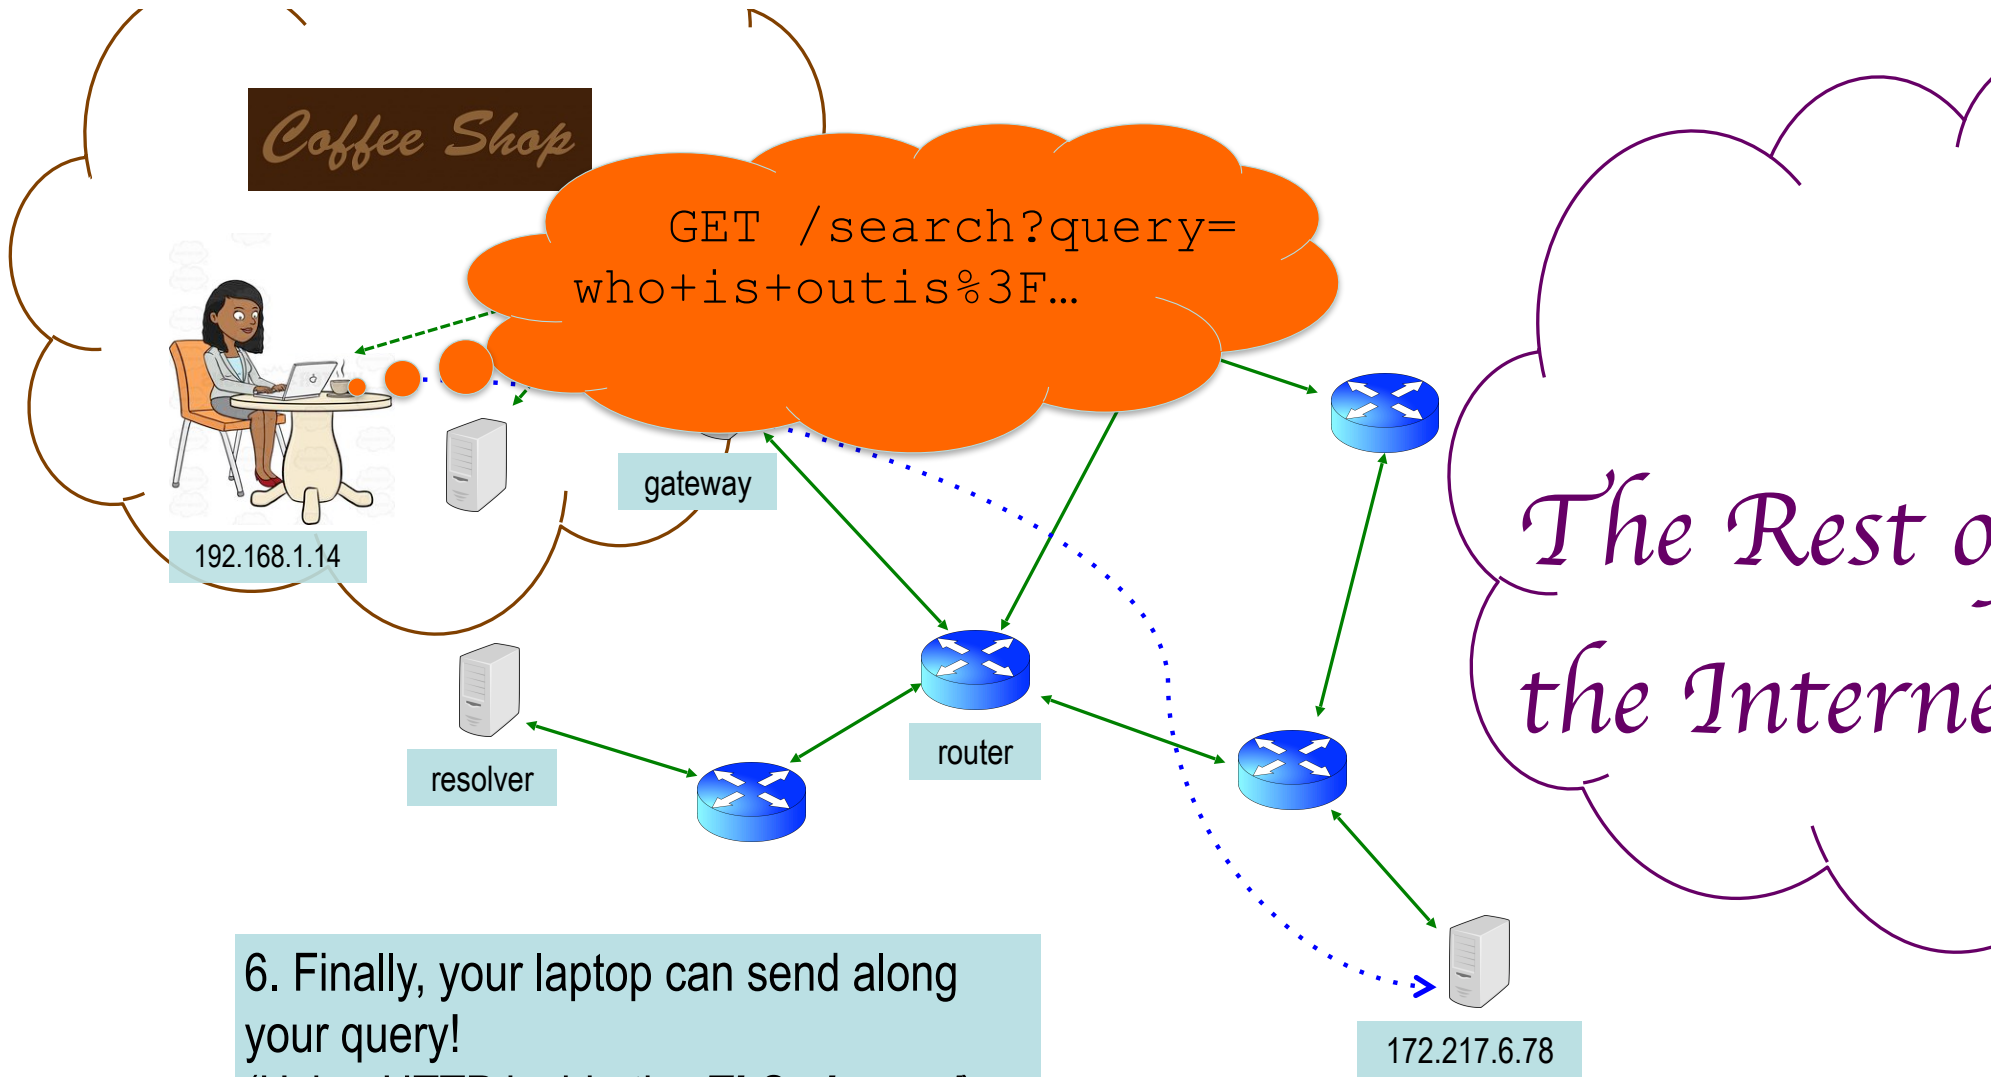

Well if you really possess the corresponding private key, prove it by signing your Diffie/Hellman half of a DHE using the private key? (DHE/ECDHE key exchange)

The Rest of the Internet

5. Establish a secure connection using **TLS** (https)

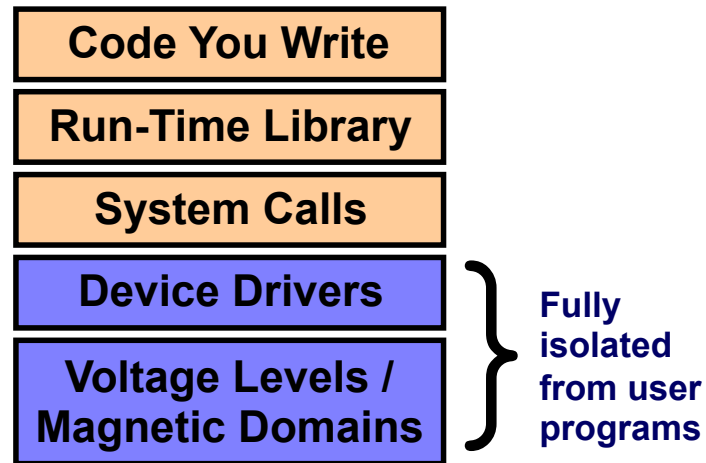

5. Establish a secure connection using **TLS** (https)

6. Finally, your laptop can send along your query!
(Using HTTP inside the **TLS channel**)

Layering

- Internet design is strongly partitioned into **layers**
- Each layer relies on services provided by next layer below ...
- ... and provides services to layer above it
- **Analogy:**
 - Consider structure of an application you've written and the "services" each layer relies on / provides

Internet Layering (“Protocol Stack”/“OSI Model”)

Note on a point of potential confusion: these diagrams are always drawn with lower layers **below** higher layers ...

But diagrams showing the layouts of packets are often the *opposite*, with the lower layers at the **top** since their headers precede those for higher layers

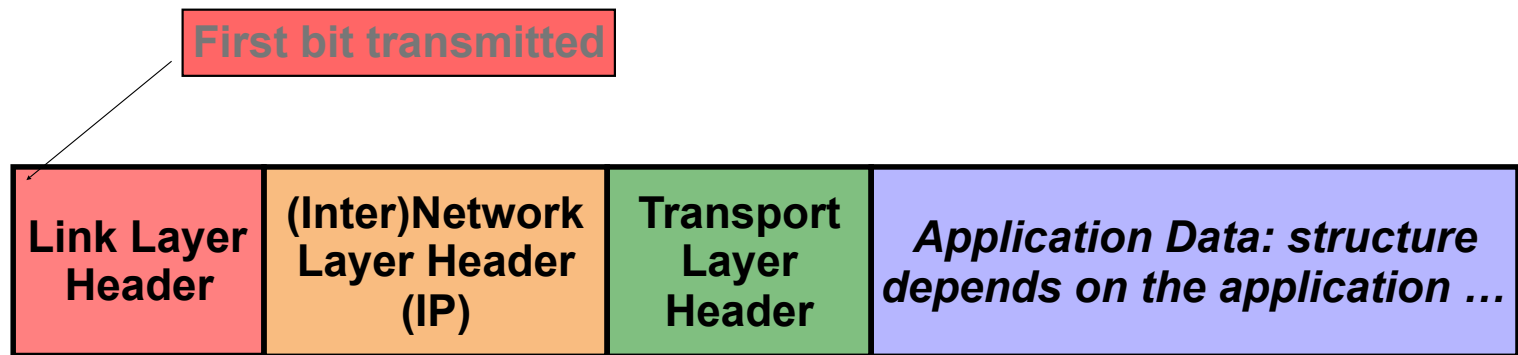

(And nobody remembers what layers 5 and 6 are for (“Session” and “Presentation”) for the trivia buffs because they aren’t really used)

(also, layer 8 is a “joke”, but really is important)

Packets and The Network

- Modern networks break communications up into packets
 - For our purposes, packets contain a variable amount of data up to a maximum specified by the particular network
- The sending computer breaks up the message and the receiving computer puts it back together
 - So the software doesn't actually see the packets per-se
 - Network itself is **packet switched**: sending each packet on towards its next destination
- Other properties:
 - Packets are received **correctly** or not at all in the face of **random** errors
 - The network does not enforce correctness in the face of adversarial inputs: They are checksums not cryptographic MACs.
 - Packets may be **unreliable** and “dropped”
 - Its up to higher-level protocols to make the connection Reliable

Horizontal View of a Single Packet

Vertical View of a Single Packet

Internet Layering (“Protocol Stack”)

Layer 1: Physical Layer

Encoding **bits** to send them over a single physical link e.g. patterns of *voltage levels / photon intensities / RF modulation*

Layer 2: Link Layer

Framing and transmission of a collection of bits into individual **messages** sent across a single “subnetwork” (one physical technology)

Might involve multiple *physical links* (e.g., modern Ethernet)

Often technology supports **broadcast** transmission (**every** “node” connected to subnet receives)

Layer 3: (Inter)Network Layer (*IP*)

Bridges multiple “subnets” to provide *end-to-end* internet connectivity between nodes

- Provides global addressing

Works across **different** link technologies

Different for each Internet “hop”

Layer 4: Transport Layer

End-to-end communication between **processes**

Different services provided:
TCP = reliable *byte stream*
UDP = unreliable *datagrams*

(Datagram = single packet message)

Layer 7: Application Layer

Communication of whatever you wish

Can use whatever transport(s) is convenient

Freely structured

E.g.:

Skype, SMTP (email),
HTTP (Web), Halo, BitTorrent

4.5: Some Crypto...

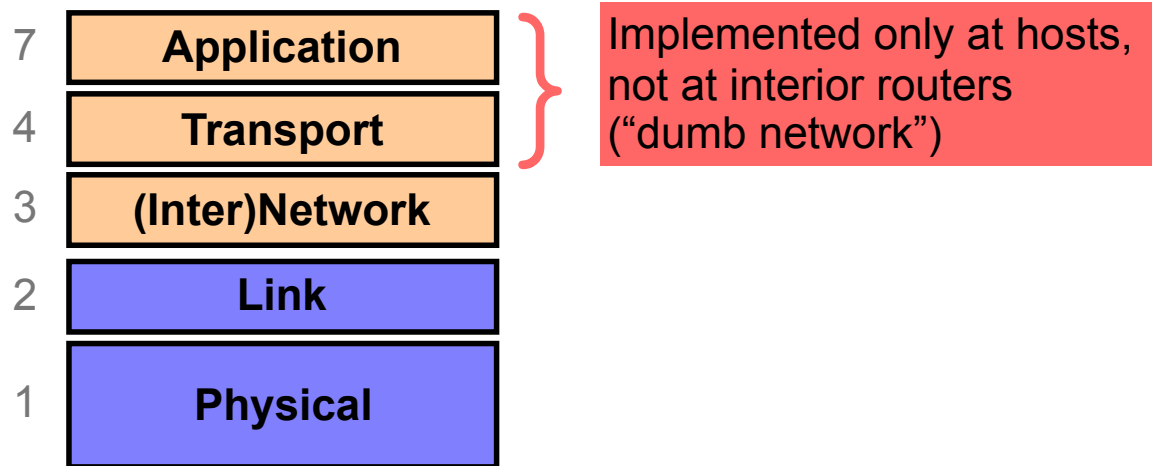

TLS cryptography
(aka the 's' in HTTPS)

Often basically used as a
"layer 4.5" transport layer to
encrypt otherwise
unencrypted network
connections

Other times crypto may be at
the application layer (e.g. ssh)

Internet Layering (“Protocol Stack”)

Internet Layering (“Protocol Stack”)

Internet Layering (“Protocol Stack”)

Hop-By-Hop vs. End-to-End Layers

Host A communicates with Host D

Hop-By-Hop vs. End-to-End Layers

Host A communicates with Host D

Different Physical & Link Layers (Layers 1 & 2)

Hop-By-Hop vs. End-to-End Layers

Host A communicates with Host D

E.g., HTTP over TCP over IP

Same Network / Transport / Application Layers (3/4/7)
(Routers **ignore** Transport & Application layers)

Layer 3: (Inter)Network Layer (*IP*)

Bridges multiple “subnets” to provide *end-to-end* internet connectivity between nodes

- Provides global addressing

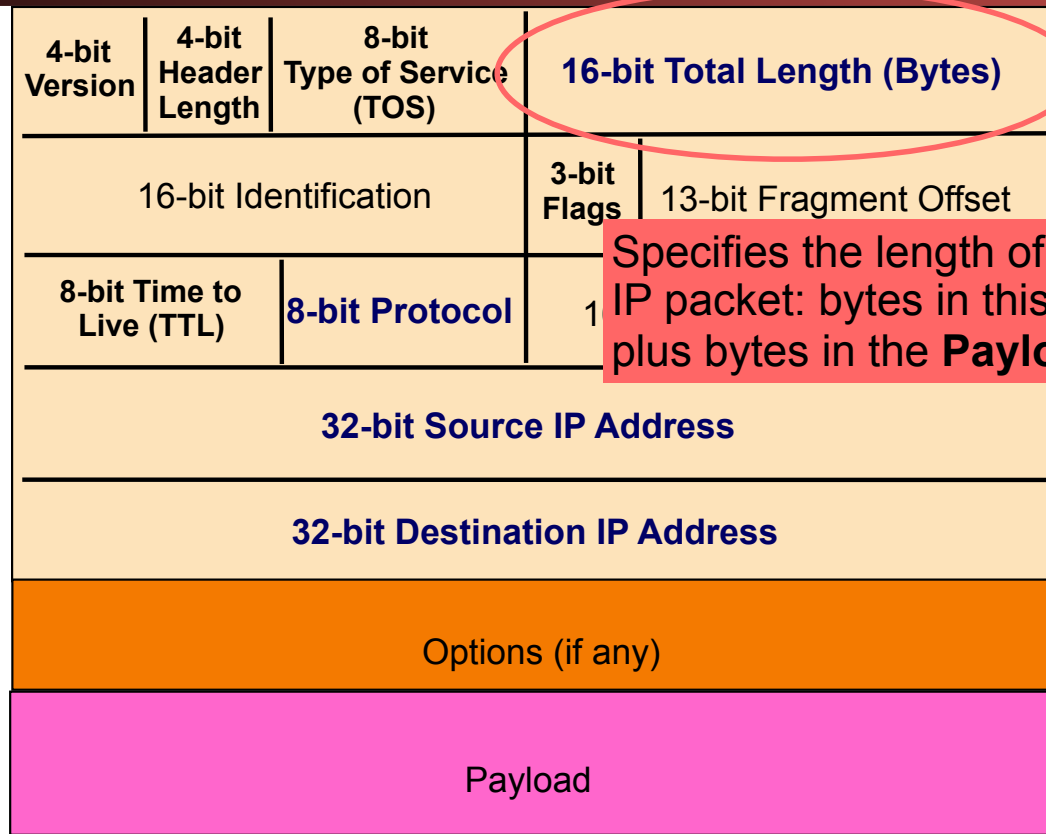

Works across different link technologies

IPv4 Packet Structure

(IP version 6 is different)

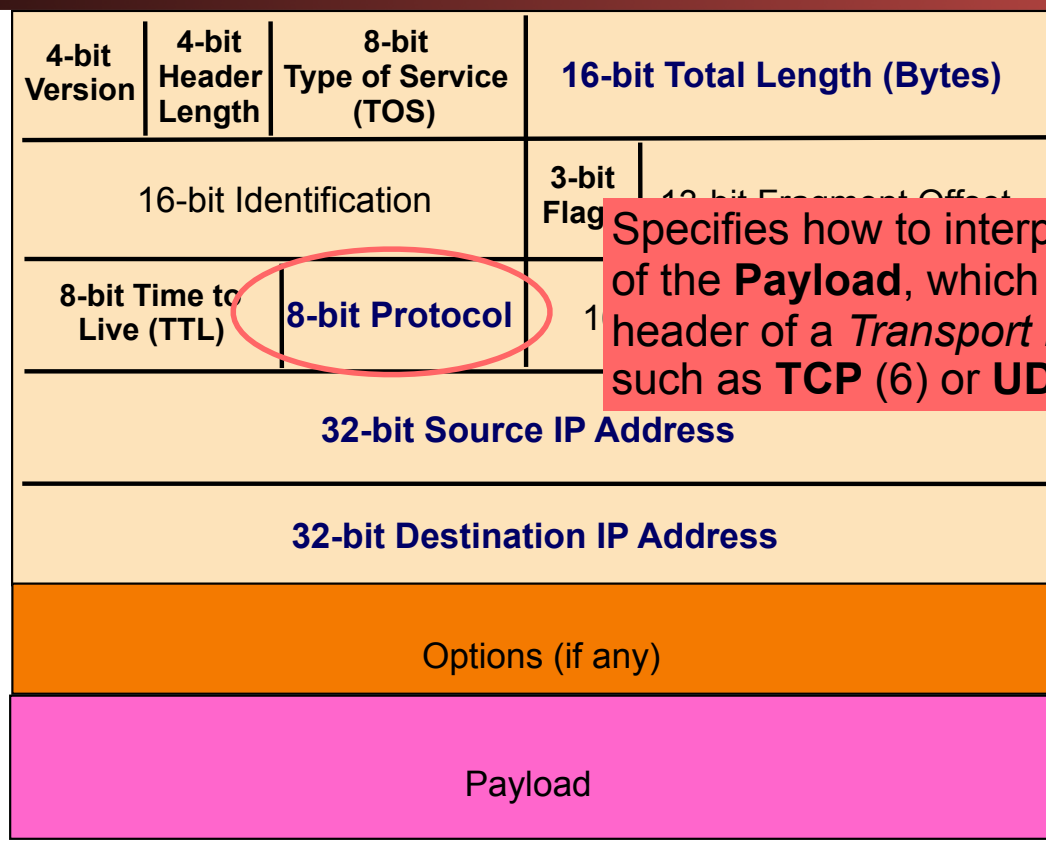

4-bit Version	4-bit Header Length	8-bit Type of Service (TOS)	16-bit Total Length (Bytes)	
16-bit Identification			3-bit Flags	13-bit Fragment Offset
8-bit Time to Live (TTL)	8-bit Protocol		16-bit Header Checksum	
32-bit Source IP Address				
32-bit Destination IP Address				
Options (if any)				
Payload				

IP Packet Structure

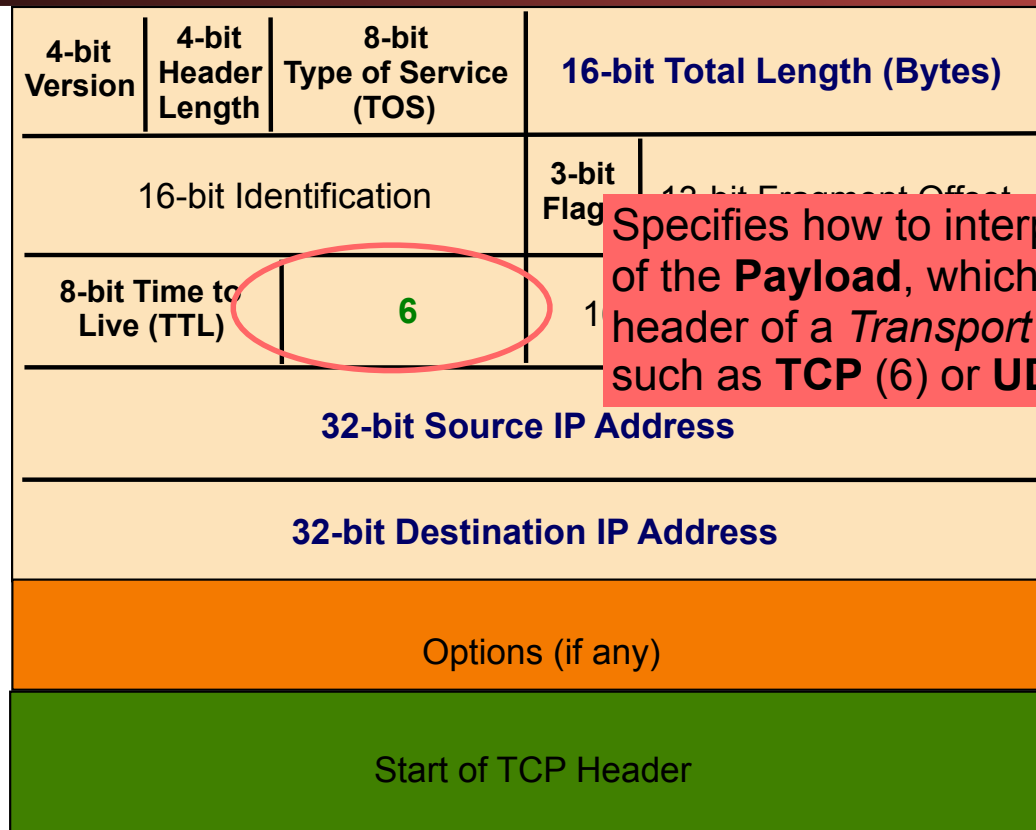

Specifies the length of the entire IP packet: bytes in this header plus bytes in the **Payload**

IP Packet Structure

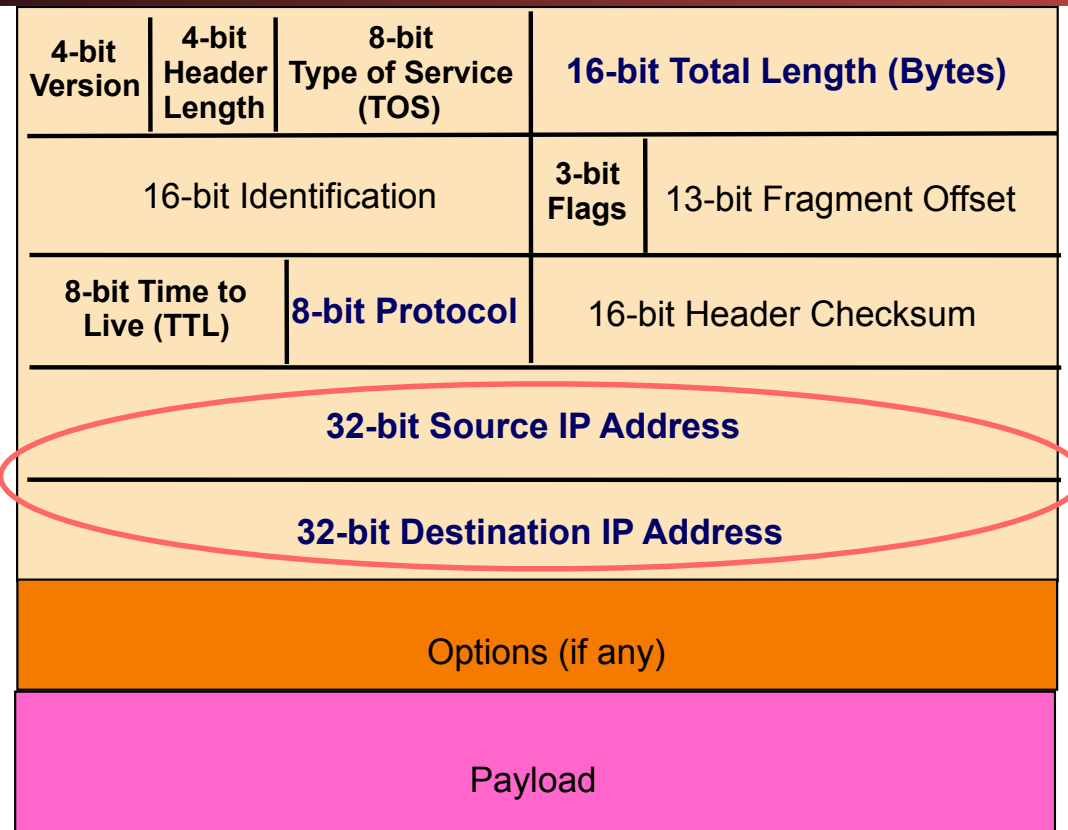

Specifies how to interpret the start of the **Payload**, which is the header of a *Transport Protocol* such as **TCP** (6) or **UDP** (17)

IP Packet Structure

Specifies how to interpret the start of the **Payload**, which is the header of a *Transport Protocol* such as **TCP** (6) or **UDP** (17)

IP Packet Structure

IP Packet Header (Continued)

- Two IP addresses
 - Source IP address (32 bits in main IP version, IPv4)
 - Destination IP address (32 bits, likewise)
- Destination address
 - Unique **identifier/locator** for the receiving host
 - Allows each node to make forwarding decisions
- Source address
 - Unique identifier/locator for the sending host
 - Recipient can decide whether to accept packet
 - Enables recipient to send reply back to source

The Basic Ethernet Packet: The near-universal Layer 2

- An Ethernet Packet contains:
 - A preamble to synchronize data on the wire
 - We normally ignore this when talking about Ethernet
 - 6 bytes of destination MAC address
 - In this case, MAC means media access control address, not message authentication code!
 - 6 bytes of source MAC address
 - Optional 4-byte VLAN tag
 - 2 bytes length/type field
 - 46-1500B of payload

DST MAC	SRC MAC	VLAN	Type	PAYLOAD
---------	---------	------	------	---------

The MAC Address

- The MAC acts as a device identifier
 - The upper 3 bytes are assigned to a manufacturer
 - Can usually identify product with just the MAC address
 - The lower 3 bytes are assigned to a specific device
 - Making the MAC a de-facto serial #
- Usually written as 6 bytes in hex:
 - e.g. `13:37:ca:fe:f0:0d`
- A device ***should ignore*** all packets that aren't to itself or to the broadcast address (`ff:ff:ff:ff:ff:ff`)
 - But almost all devices can go into ***promiscuous mode***
 - This is also known as "sniffing traffic"
- A device generally should only send with its own address
 - But this is enforced with software and can be trivially bypassed when you need to write "raw packets"
