The Net Part 3: DNS...

Security 🤦 Of The Day: New York Times Edition

Types of Network Attackers...

- Off Path: 😑 I see NOTHING
  - Attacker is unable to see the network traffic of the victim
- On Path/Man On The Side: 🧐 I see you
  - Attacker can see packets...
  - Attacker can also add packets 📣
  - Attacker ***can not*** block legitimate packets
- In Path/Man In The Middle: 🤬 I see you and can censor you
  - Attacker can see packets
  - Attacker can add packets
  - Attacker can block legitimate packets
    - Together the attacker can ***replace*** packets

Actually Making it Secure: WPA Enterprise

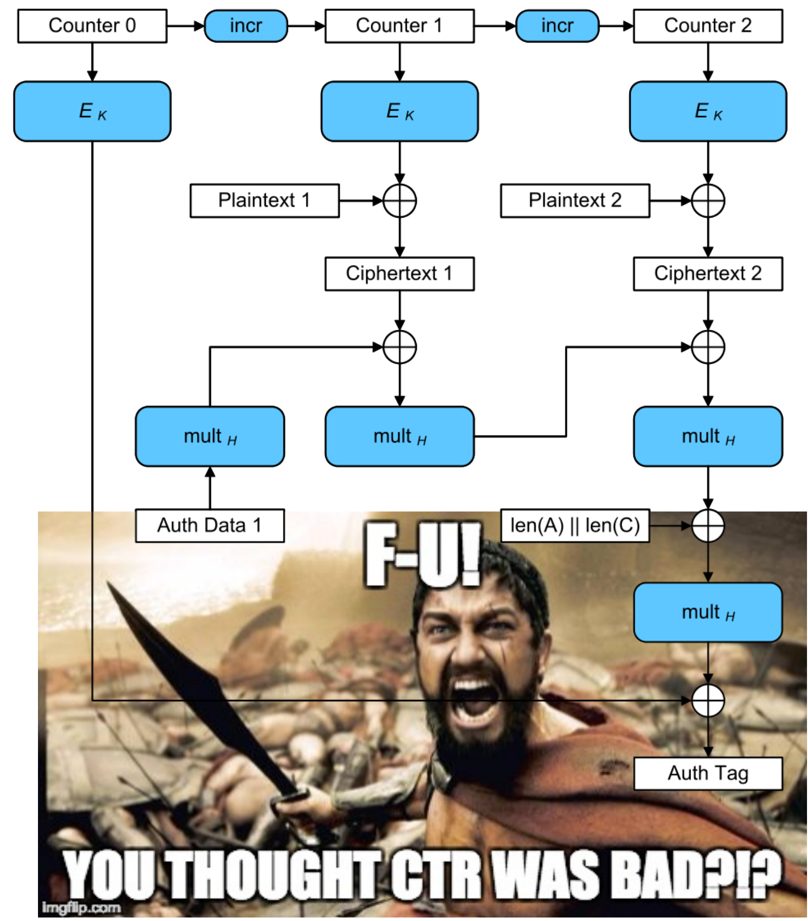
- When you set up Airbears 2, it asks you to accept a public key certificate
  - This is the public key of the authentication server
- Now before the 4-way handshake:
  - Your computer first handshakes with the authentication server
    - This is secure using public key cryptography
  - Your computer then authenticates to this server
    - With your username and password
- The server now generates a unique key that it both tells your computer and tells the base station
  - So the 4 way handshake is now secure

The Latest Hotness: KRACK attack...

- To actually encrypt the individual packets: IV of a packet is {Agreed IV || packet counter}
  - Thus for each packet you only need to send the packet counter (48 bits) rather than the full IV (128b)
- Multiple different modes
  - One common one is CCM (Counter with CBC-MAC)
    - MAC the data with CBC-MAC
      Then encrypt with CTR mode
  - The highest performance is GCM (Galois/Counter Mode)
- But if you thought CTR mode was bad on IV reuse...
  - GCM is worse: A couple of reused IVs can reveal enough information to forge the authentication!
- Discovered a couple years ago, fairly quickly patch, but...

GCM...

- GCM is like CTR mode with a twist...
  - The confidentiality is pure CTR mode
  - The "Galois" part is a hash of the cipher text
    - The only secret part being the "Auth Data"
- Reuse the IV, what happens?
  - Not ***only*** do you have CTR mode loss of confidentiality...
  - But if you do it enough, you lose confidentiality on the Auth Data...
  - So you lose the integrity that GCM supposedly provided!



And Packets Get "Lost"

- Even a wired network will "drop packets"
  - A message is sent but simply never delivered
- Its far worse on wireless
  - A gazillion things can go wrong, including other transmitters
    - And noise like a microwave oven!
- So you have to design for packets to be rebroadcast...
- In the WPA handshake, what do you do when you receive the 3rd packet?
  - Initialize the key you use for encrypting the packets
  - Set the packet counter to 0

And A Replay Attack...

- What if the attacker listens for the third step in the handshake...
  - And then repeats it?
- Why, the client is supposed to reinitialize the key and agreed IV...
  - Which on many implementations, ***also resets the packet counter***...
  - Oh, and Linux (and Android 6) is worse... It reinitializes the key ***to zero!***
- So what does that mean?

Attack Scenario...

- Attacker is close to target
- Attacker captures the 3rd step in the handshake
- Attacker repeatedly replays this to the client
- Client now repeats IVs for encryption...
- Other modes. Annoyance: the damage is minor
- CCM-mode: Attacker can now decrypt in practice thanks to IV reuse
- GCM-mode...
  - Attacker can now decrypt ***and forge packets***:
    Reusing the IV also reveals the MAC-secret!

Mitigations...

- Like all attacks on WiFi, it requires a "close" attacker...
  - 100m to a km or two...
- If you use WPA2-PSK, aka a "WiFi Password", who cares?
  - Unless your WiFi password sounds like a cat hawking up a hairball, you don't have enough entropy to resist a brute-force attacks
- If you use WPA2-Enterprise, this ***may*** matter...
  - But lets face it, there are so many more critical things to patch first...
  - And why are you treating the WiFi as trusted anyway?

But Broadcast Protocols Make It Worse...

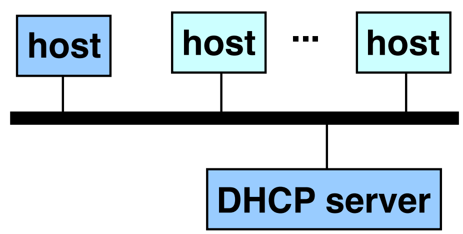
- By default, both DHCP and ARP broadcast requests
  - Sent to ***all*** systems on the local area network
- DHCP: Dynamic Host Control Protocol
  - Used to configure all the important network information
    - Including the DNS server:
      If the attacker controls the DNS server they have complete ability to intercept all traffic!
    - Including the Gateway which is where on the LAN a computer sends to:
      If the attacker controls the gateway
- ARP: Address Resolution Protocol
  - "Hey world, what is the Ethernet MAC address of IP X"
  - Used to find both the Gateway's MAC address and other systems on the LAN

Coffee Shop

2. Configure your connection

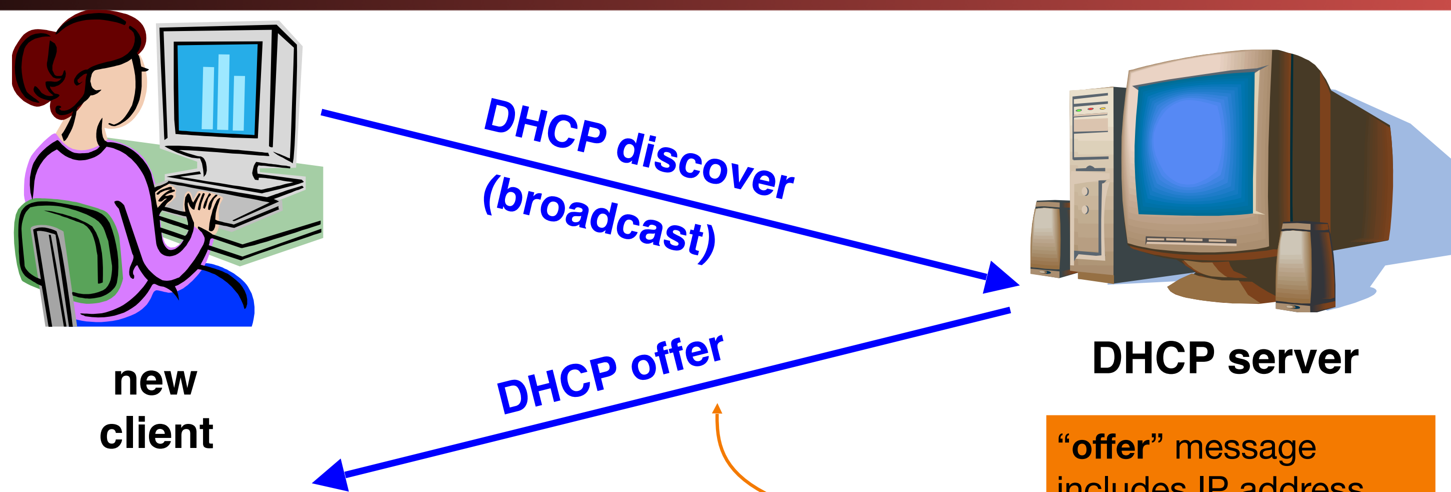
Internet Bootstrapping: DHCP

- New host doesn't have an IP address yet
  - So, host doesn't know what source address to use
- Host doesn't know *who to ask* for an IP address
  - So, host doesn't know what destination address to use
- (Note, host does have a separate WiFi address)
- Solution: *shout* to "**discover**" server that can help
  - Broadcast a server-discovery message (layer 2)
  - Server(s) sends a reply offering an address



DHCP = Dynamic Host Configuration Protocol

Dynamic Host Configuration Protocol

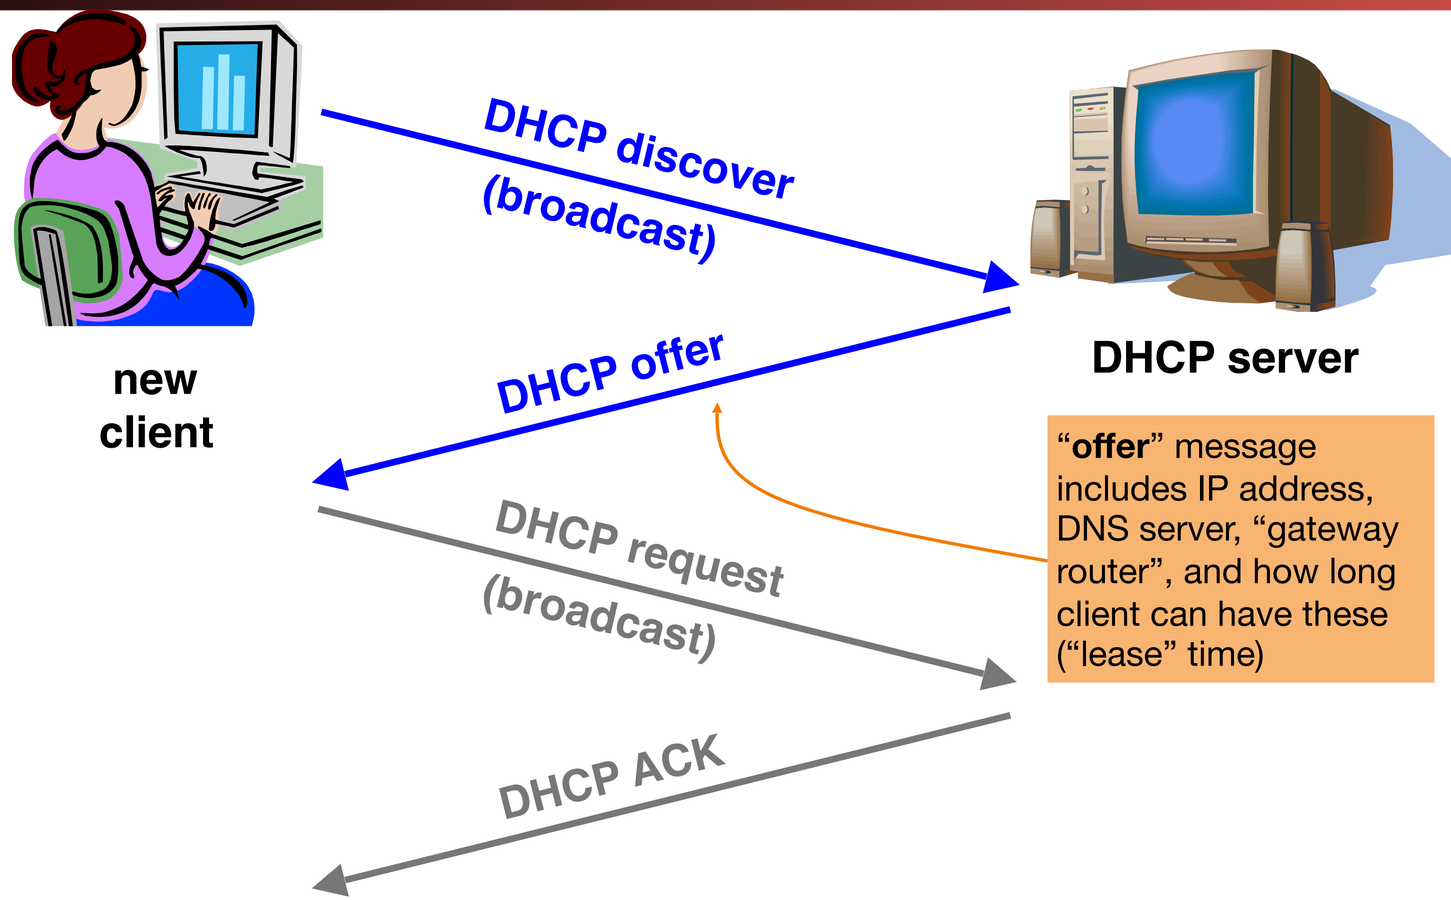


"**offer**" message includes IP address, DNS server, "gateway router", and how long client can have these ("lease" time)

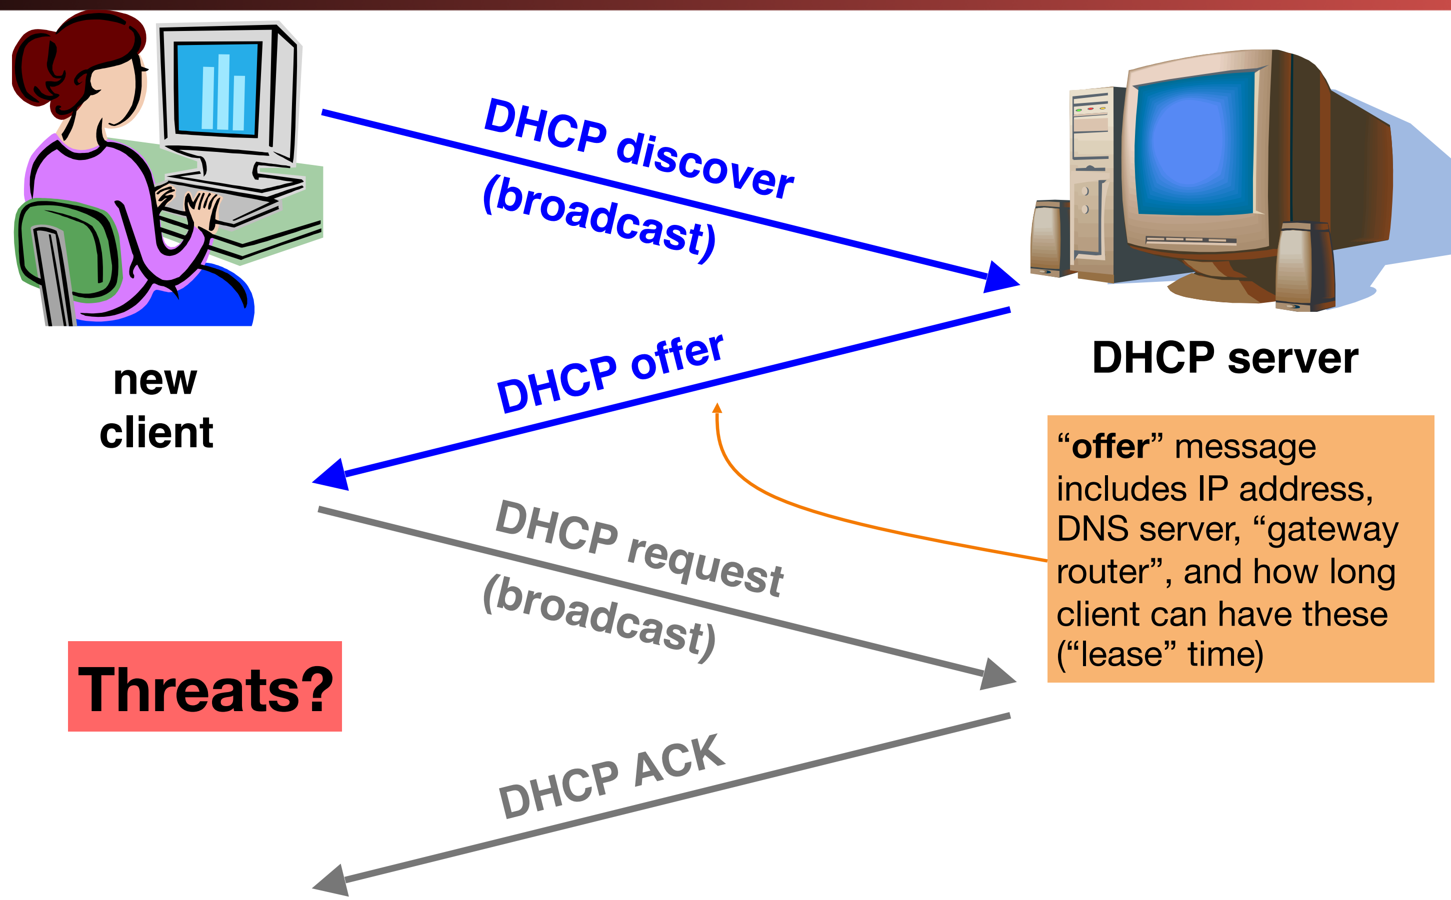
DNS server = system used by client to map hostnames like `gmail.com` to IP addresses like `74.125.224.149`

Gateway router = router that client uses as the first hop for all of its Internet traffic to remote hosts

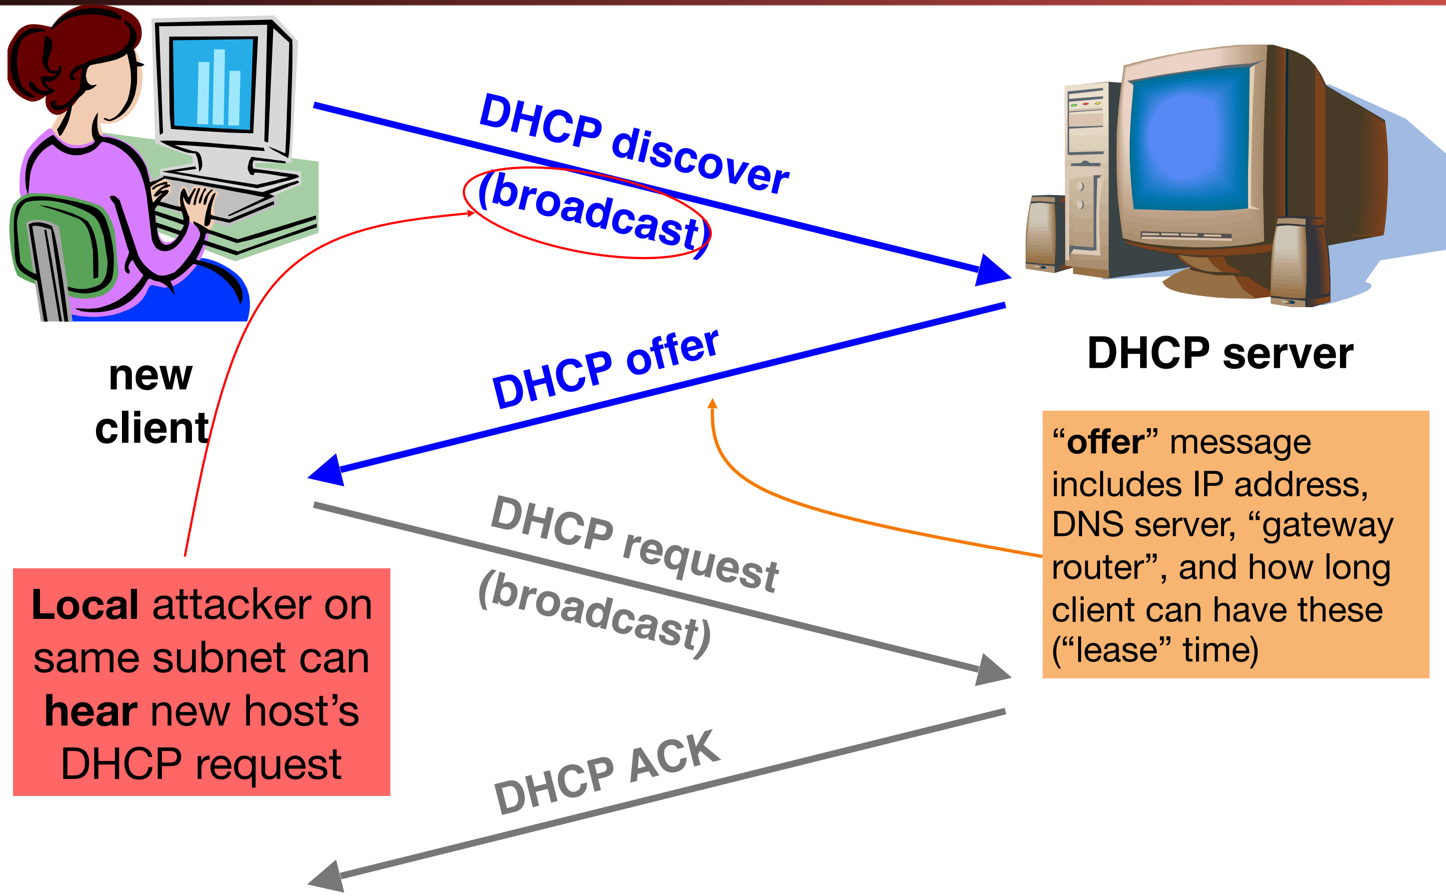
Dynamic Host Configuration Protocol



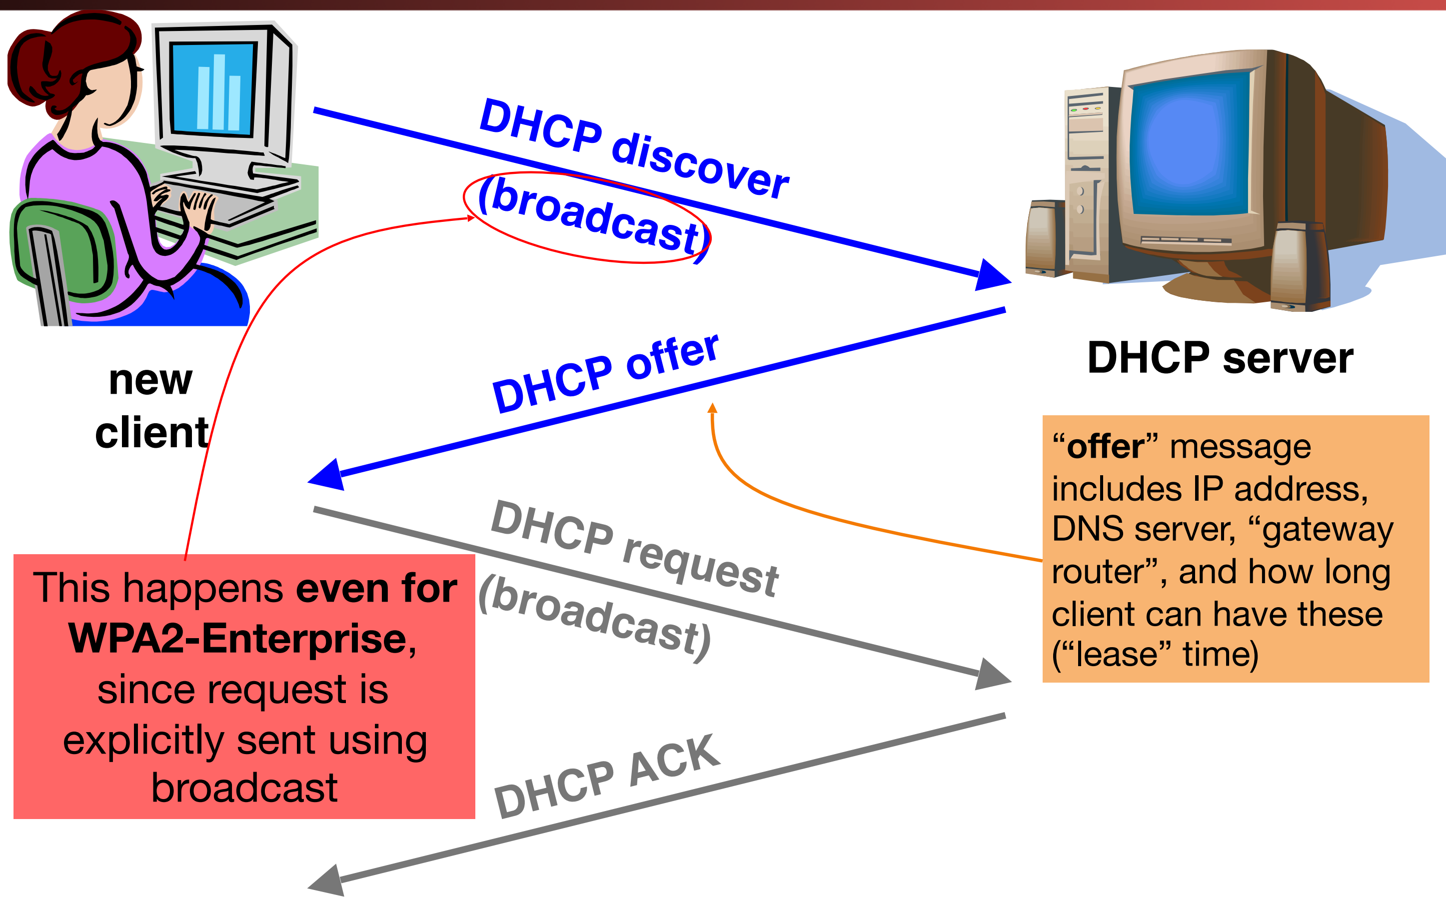
Dynamic Host Configuration Protocol



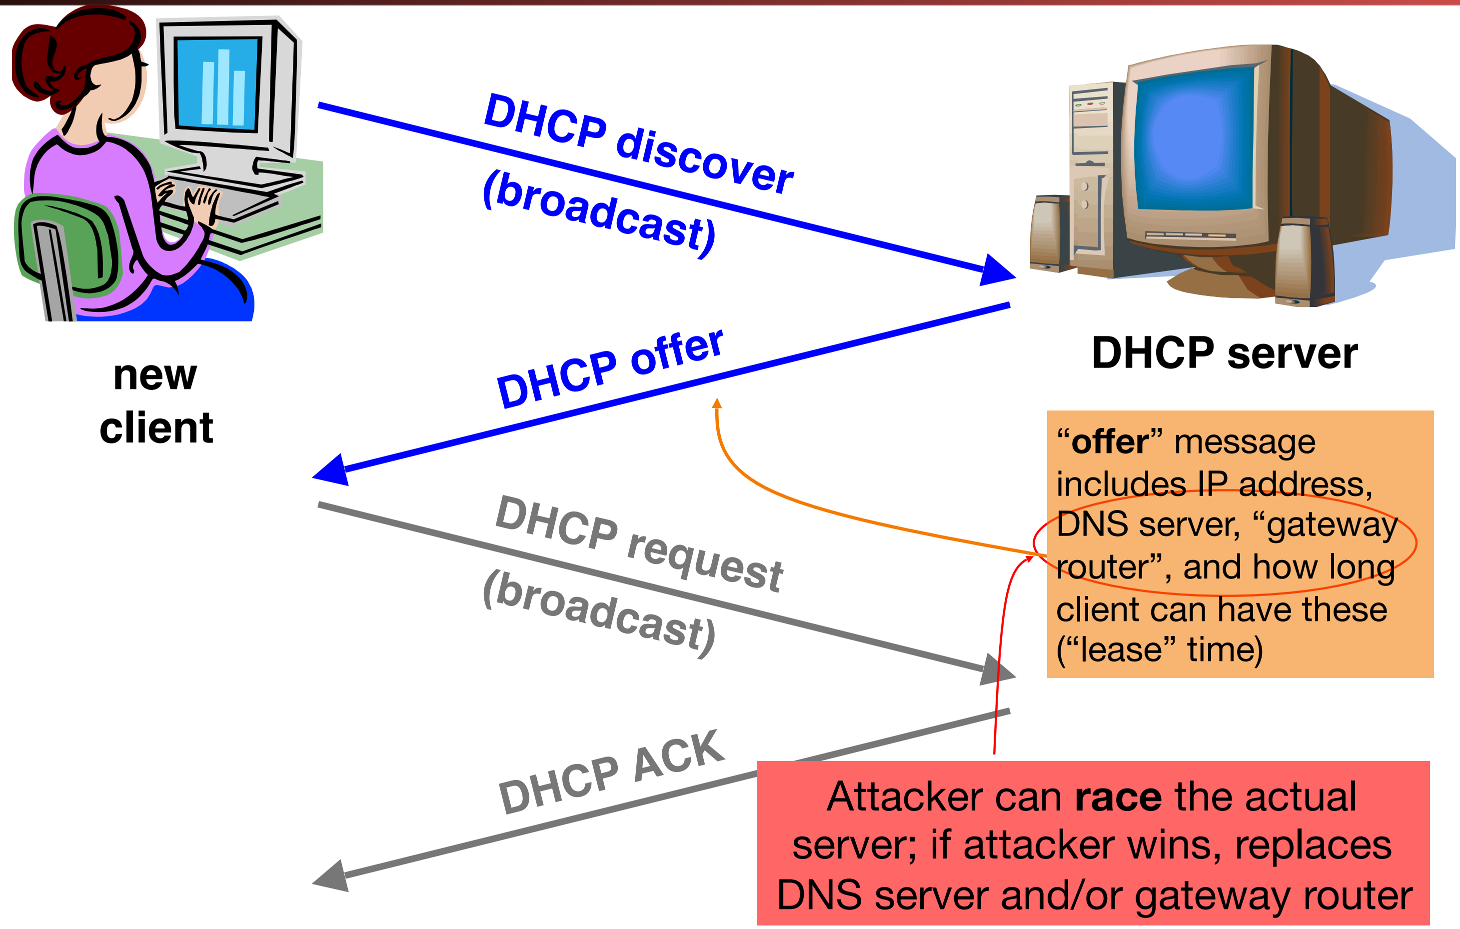
Dynamic Host Configuration Protocol



Dynamic Host Configuration Protocol



Dynamic Host Configuration Protocol



DHCP Threats

- Substitute a fake DNS server
  - Redirect any of a host's lookups to a machine of attacker's choice (e.g., `gmail.com` = `6.6.6.6`)
- Substitute a fake gateway router
  - Intercept all of a host's off-subnet traffic
  - Relay contents back and forth between host and remote server
    - Modify however attacker chooses
  - This is one type of invisible Man In The Middle (MITM)
    - Victim host generally has no way of knowing it's happening! 😟
    - (Can't necessarily alarm on peculiarity of receiving multiple DHCP replies, since that can happen benignly)
- How can we fix this?

Hard, because we lack a ***trust anchor***

DHCP Conclusion

- DHCP threats highlight:
  - Broadcast protocols inherently at risk of local attacker spoofing
    - Attacker knows exactly when to try it …
    - … and can see the victim's messages
  - When initializing, systems are particularly vulnerable because they can lack a trusted foundation to build upon
  - Tension between ***wiring in trust*** vs. ***flexibility and convenience***
  - MITM attacks insidious because no indicators they're occurring

So How Do We Secure the LAN?

- Option 1: We don't
  - Just assume we can keep bad people out...
    - Or don't trust the LAN at all: treat it like the rest of the Internet
  - This is how most people run their networks:
    "Hard on the outside with a goey chewy caramel center"
- Option 2: ***smart*** switching and active monitoring

The Switch

- Hubs are very inefficient:
  - By broadcasting traffic to all recipients this greatly limits the aggregate network bandwidth
- Instead, most Ethernet uses switches
  - The switch keeps track of which MAC address is seen where
- When a packet comes in:
  - If it is to the broadcast address, send it to all ports
  - If there is no entry in the MAC cache for the destination, broadcast it to all ports
  - If there is an entry, send it just to that port
- Result is vastly improved bandwidth
  - All ports can send or receive at the same time

Smarter Switches: Clean Up the Broadcast Domain

- Modern high-end switches can do even more
  - A large amount of potential packet processing on items of interest
- Basic idea: constrain the broadcast domain
  - Either filter requests so they only go to specific ports
    - Limits other systems from listening
  - Or filter replies
    - Limits other systems from replying
- Locking down the LAN is very important practical security
  - This is ***real*** defense in depth:
    Don't want 'root on random box, pwn whole network'
  - This removes "***pivots***" the attacker can try to extend a small foothold into complete network ownership
- This is why an Enterprise switch may cost $1000s yet provide no more real bandwidth than a $100 Linksys.

Smarter Switches:
Virtual Local Area Networks (VLANs)

- Our big expensive switch can connect a lot of things together
  - But really, many are in ***different*** trust domains:
    - Guest wireless
    - Employee wireless
    - Production desktops
    - File Servers
    - etc...
- Want to isolate the different networks from each other
  - Without actually buying separate switches

VLANs

- An ethernet port can exist in one of two modes:
  - Either on a single VLAN
  - On a trunk containing multiple specified VLANs
- All network traffic in a given VLAN stays only within that VLAN
  - The switch makes sure that this occurs
- When moving to/from a trunk the VLAN tag is added or removed
  - But still enforces that a given trunk can only read/write to specific VLANs

Putting It Together:
If I Was In Charge of UC networking...

- I'd isolate networks into 3+ distinct classes
  - The plague pits (AirBears, Dorms, etc)
  - The mildly infected pits (Research)
  - Administration
- Administration would be locked down
  - Separate VLANs
  - Restricted DHCP/system access
  - Isolated from the rest of campus

Addressing on the Layers On The Internet

- Ethernet:
  - Address is 6B MAC address, Identifies a machine on the local LAN
- IP:
  - Address is a 4B (IPv4) or 16B (IPv6) address, Identifies a system on the Internet
- TCP/UDP:
  - Address is a 2B port number, Identifies a particular listening server/process/activity on the system
    - Both the client and server have to have a port associated with the communication
  - Ports 0-1024 are for privileged services
    - Must be root to accept incoming connections on these ports
    - Any thing can do an outbound request to such a port
  - Port 1025+ are for anybody
    - And high ports are often used ephemerally

UDP:
Datagrams on the Internet

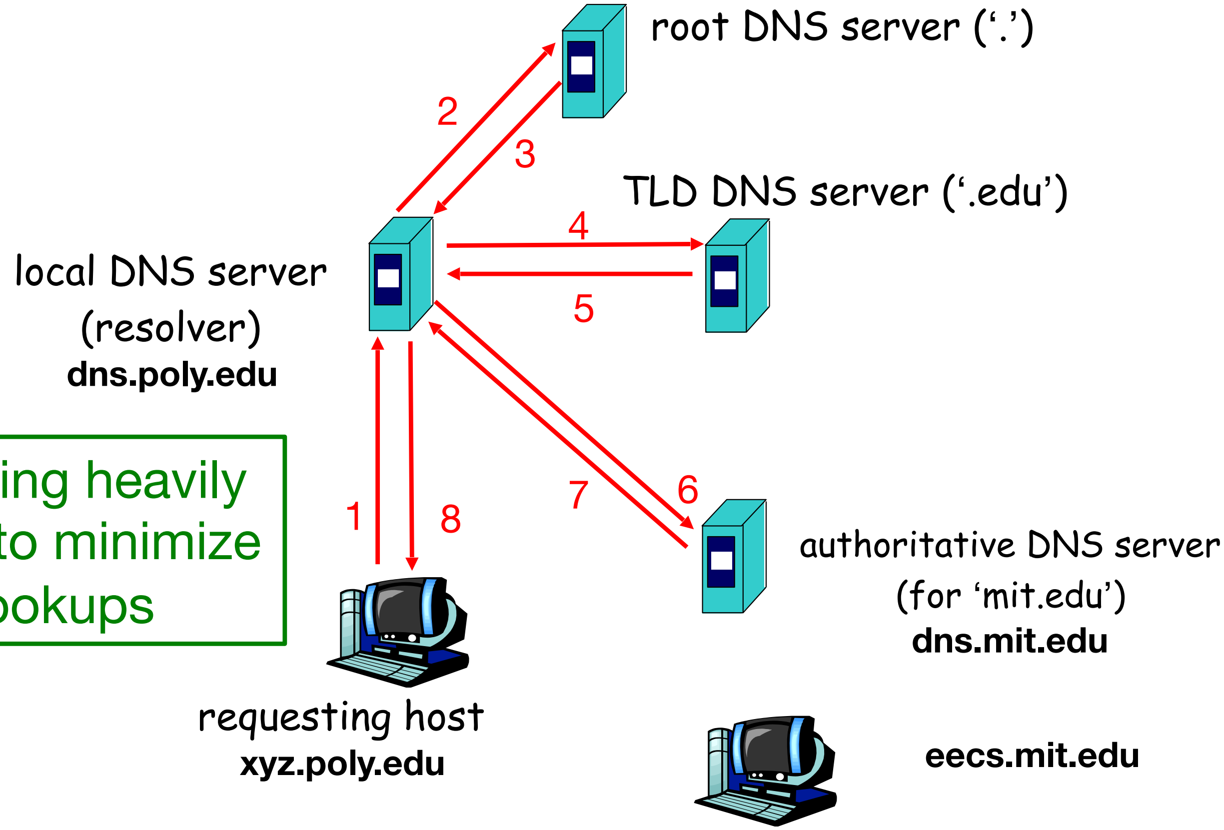
- UDP is a protocol built on the Internet Protocol (IP)
- It is an "unreliable, datagram protocol"
  - Messages may or may not be delivered, in any order
  - Messages can be larger than a single packet (but probably shouldn't)
    - IP will fragment these into multiple packets (mostly... Single digit %-age of hosts can't receive fragmented traffic)
- Programs create a socket to send and receive messages
  - Just create a datagram socket for an ephemeral port
  - Bind the socket to a particular port to receive traffic on a specified port
  - Basic recipe for Python: https://wiki.python.org/moin/UdpCommunication

DNS Overview

- DNS translates www.google.com to 74.125.25.99
  - Turns a human abstraction into an IP address
  - Can also contain other data
- It's a performance-critical distributed database.
- DNS security is critical for the web.
  (Same-origin policy ***assumes*** DNS is secure.)
  - Analogy: If you don't know the answer to a question, ask a friend for help (who may in turn refer you to a friend of theirs, and so on).
- Based on a notion of hierarchical trust:
  - You trust . for everything, com. for any com, google.com. for everything google…

DNS Lookups via a *Resolver*

Host at **`xyz.poly.edu`** wants IP address for **`eecs.mit.edu`**



Caching heavily used to minimize lookups

Security risk #1: malicious DNS server

- Of course, if *any* of the DNS servers queried are malicious, they can lie to us and fool us about the answer to our DNS query
- (In fact, they used to be able to fool us about the answer to other queries, too. We'll come back to that.)

Security risk #2: on-path eavesdropper

- If attacker can eavesdrop on our traffic… we're hosed.
- Why? We'll see why.

Security risk #3: off-path attacker

- If attacker can't eavesdrop on our traffic, can he inject spoofed DNS responses?
- This case is especially interesting, so we'll look at it in detail.

DNS Threats

- DNS: path-critical for just about everything we do
  - Maps hostnames ⇔ IP addresses
  - Design only **scales** if we can minimize lookup traffic
    - #1 way to do so: caching
    - #2 way to do so: return not only answers to queries, but additional info that will likely be needed shortly
      - The "glue records"
- What if attacker eavesdrops on our DNS queries?
  - Then similar to DHCP, ARP, AirPwn etc, can spoof responses
- Consider attackers who *can't* eavesdrop - but still aim to manipulate us via *how the protocol functions*
- Directly interacting w/ DNS: **`dig`** program on Unix
  - Allows querying of DNS system
  - Dumps each field in DNS responses

```
dig eecs.mit.edu A
```

Use Unix "`dig`" utility to look up IP address ("`A`") for hostname `eecs.mit.edu` via DNS

W20NS.mit.edu.          126738  IN      A       18.70.0.160
```

What could happen if the mit.edu server returns the following to us instead?

dig eecs.mit.edu A

```
; ; <<>> DiG 9.6.0-APPLE-P2 <<>> eecs.mit.edu a
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 19901
;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 3, ADDITIONAL: 3

;; QUESTION SECTION:
;eecs.mit.edu.                  IN      A

;; ANSWER SECTION:
eecs.mit.edu.

;; AUTHORITY SECTION:
mit.edu.                11088   IN      NS      BITSY.mit.edu.
mit.edu.                11088   IN      NS      W20NS.mit.edu.
mit.edu.                11088   IN      NS      www.berkeley.edu.

;; ADDITIONAL SECTION:
www.berkeley.edu.       100000  IN      A       18.6.6.6
BITSY.mit.edu.          166408  IN      A       18.72.0.3
W20NS.mit.edu.          126738  IN      A       18.70.0.160
```

We'd dutifully store in our cache a mapping of `www.berkeley.edu` to an IP address under MIT's control. (It could have been any IP address they wanted, not just one of theirs.)

dig eecs.mit.edu A

```
; ; <<>> DiG 9.6.0-APPLE-P2 <<>> eecs.mit.edu a
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 19901
;; flags: qr rd ra; QUERY: 1, ANSWER: 1, AUTHORITY: 3, ADDITIONAL: 3

;; QUESTION SECTION:
;eecs.mit.edu.                  IN      A

;; ANSWER SECTION:
eecs.mit.edu.           2                                6

;; AUTHORITY SECTION:
mit.edu.                11088   IN      NS      BITSY.mit.edu.
mit.edu.                11088   IN      NS      W20NS.mit.edu.
mit.edu.                11088   IN      NS      www.berkeley.edu.

;; ADDITIONAL SECTION:
www.berkeley.edu.       100000  IN      A       18.6.6.6
BITSY.mit.edu.          166408  IN      A       18.72.0.3
W20NS.mit.edu.          126738  IN      A       18.70.0.160
```

In this case they chose to make the mapping last a long time. They could just as easily make it for just a couple of seconds.

dig eecs.mit.edu A

```
; ; <<>> DiG 9.6.0-APPLE-P2 <<>> eecs.mit.edu a
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 19901

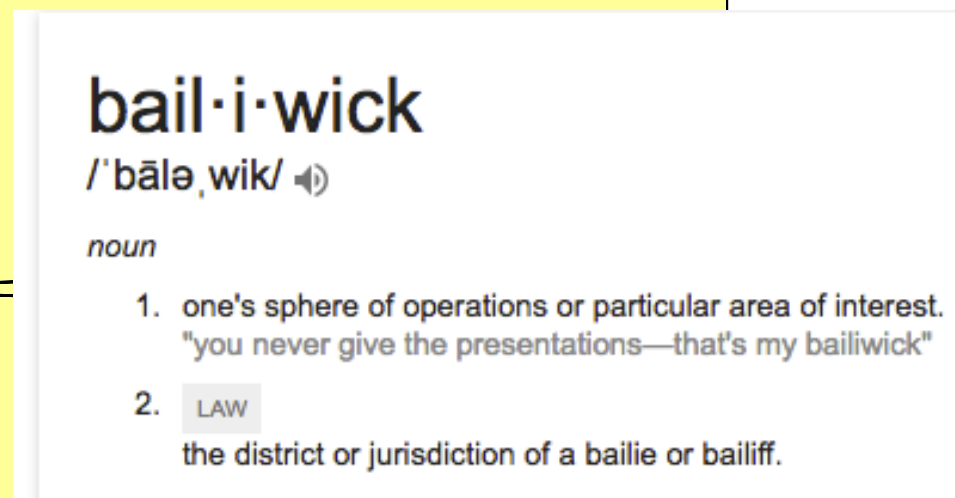
W20NS.mit.edu.          126738  IN
```

Don’t accept **Additional** records unless they’re for the domain we’re looking up

E.g., looking up `eecs.mit.edu` ⇒ only accept additional records from `*.mit.edu`

No extra risk in accepting these since server could return them to us directly in an **Answer** anyway.

This is called "***Bailiwick*** checking"



DNS Resource Records and RRSETs

- DNS records (Resource Records) can be one of various types
  - Name TYPE Value
    - Also a “time to live” field: how long in seconds this entry can be cached for
  - Addressing:
    - A: IPv4 addresses
    - AAAA: IPv6 addresses
    - CNAME: aliases, “Name X should be name Y”
    - MX: “the mailserver for this name is Y”
  - DNS related:
    - NS: “The authority server you should contact is named Y”
    - SOA: “The operator of this domain is Y”
  - Other:
    - text records, cryptographic information, etc….
- Groups of records of the same type form RRSETs:
  - E.g. all the nameservers for a given domain.

www.isc.org	A	149.20.64.42	600

Stepping Through This With **dig**

- Some flags of note:
  - +norecurse: Ask directly like a recursive resolver does
  - +trace: Act like a recursive resolver without a cache

```
nweaver% dig +norecurse slashdot.org @a.root-servers.net

;  <<>> DiG 9.8.3-P1 <<>> +norecurse slashdot.org @a.root-servers.net
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 26444
;; flags: qr; QUERY: 1, ANSWER: 0, AUTHORITY: 6, ADDITIONAL: 12

;; QUESTION SECTION:
;slashdot.org.                  IN      A

;; AUTHORITY SECTION:
org.                    172800  IN      NS      a0.org.afilias-nst.info.
...

;; ADDITIONAL SECTION:
a0.org.afilias-nst.info. 172800 IN      A       199.19.56.1
```

So in `dig` parlance

- So if you want to recreate the lookups conducted by the recursive resolver:
  - **`dig +norecurse www.isc.org @a.root-servers.net`**
  - **`dig +norecurse www.isc.org @199.19.56.1`**
  - **`dig +norecurse www.isc.org @199.6.1.30`**

Security risk #1: malicious DNS server

- Of course, if *any* of the DNS servers queried are malicious, they can lie to us and fool us about the answer to our DNS query…
- and they used to be able to fool us about the answer to other queries, too, using *cache poisoning*. Now fixed (phew).

Security risk #2: on-path eavesdropper

- If attacker can eavesdrop on our traffic… we're hosed.
- Why?

Security risk #2: on-path eavesdropper

- If attacker can eavesdrop on our traffic… we're hosed.
- Why? They can see the query and the 16-bit transaction identifier, and race to send a spoofed response to our query.
  - China does this operationally:
    - Note: You may need to use the IPv4 address of www.tsinghua.edu
  - **`dig www.benign.com @www.tsinghua.edu`**
  - **`dig www.facebook.com @www.tsinghua.edu`**

Security risk #3: off-path attacker

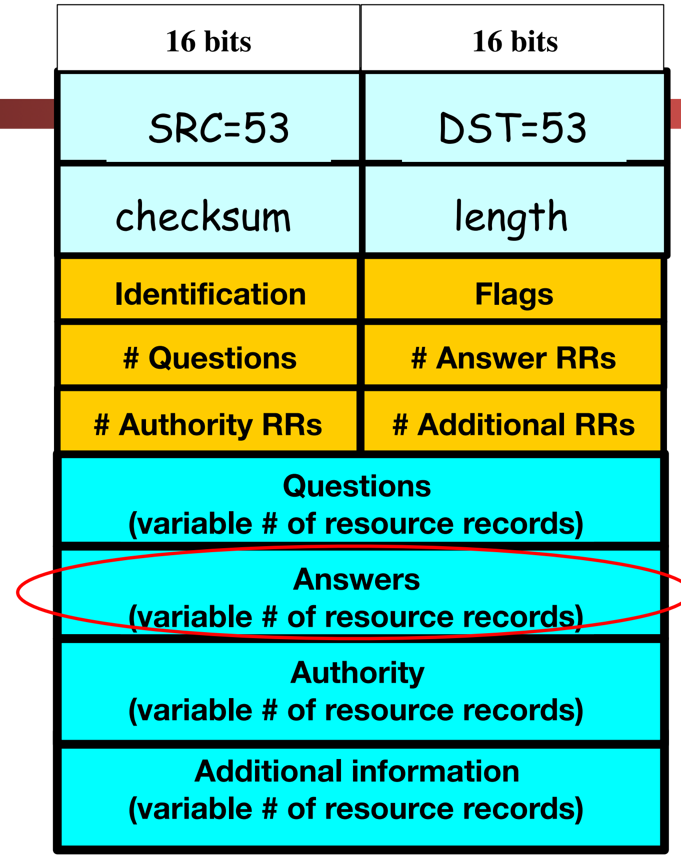
- If attacker can't eavesdrop on our traffic, can he inject spoofed DNS responses?
- Answer: It used to be possible, via *blind spoofing*. We've since deployed mitigations that makes this harder (but not totally impossible).

Blind spoofing

- Say we look up `mail.google.com`; how can an **off-path** attacker feed us a bogus `A` answer before the legitimate server replies?
- How can such a **remote** attacker even know we are looking up `mail.google.com`?

Suppose, e.g., we visit a web page under their control:

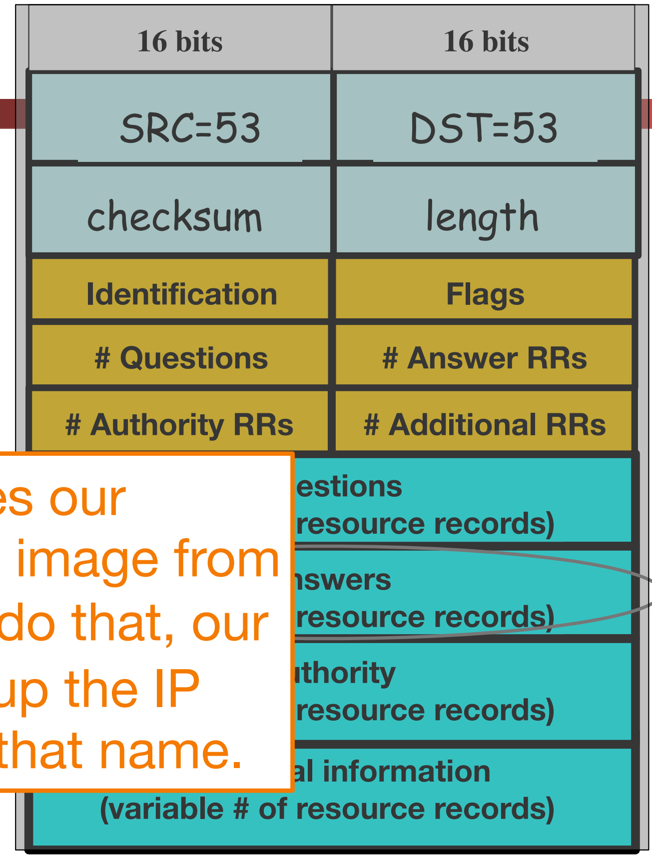
...<img src="http://mail.google.com" …> ...



Blind spoofing

- Say we look up `mail.google.com`; how can an **off-path** attacker feed us a bogus `A` answer before the legitin
- How c even k `mail` Suppose, e.g., we visit a web page under their control:

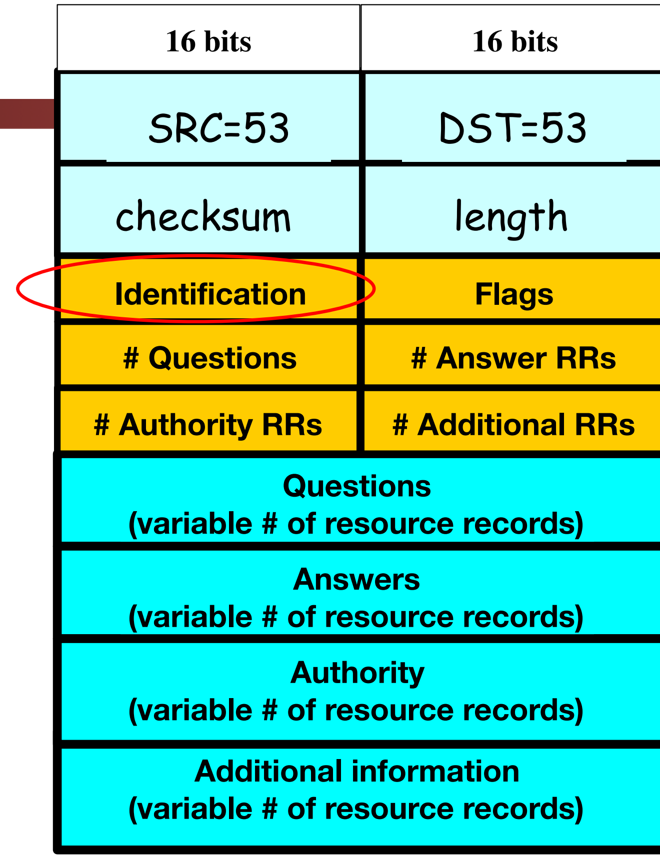
This HTML snippet causes our browser to try to fetch an image from `mail.google.com`. To do that, our browser first has to look up the IP address associated with that name.



```
...&lt;img src="http://mail.google.com" …> ...
```

Blind spoofing

Fix?



Once they know we're looking it up, they just have to guess the Identification field and reply before legit server.

How hard is that?

Originally, identification field incremented by 1 for each request. How does attacker guess it?

<img src="http://badguy.com" ...> ← They observe ID k here

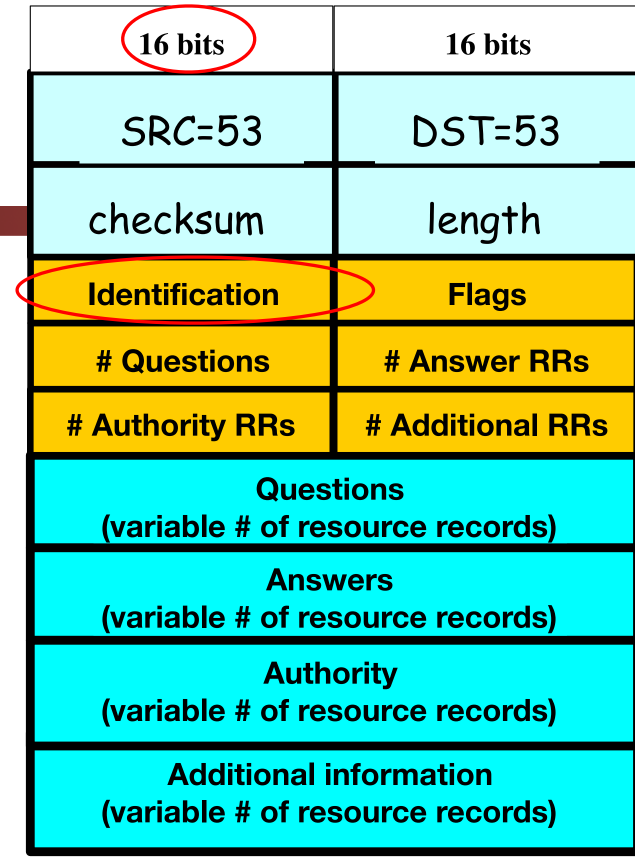
<img src="http://mail.google.com" ...> ← So this will be k+1

DNS Blind Spoofing, cont.

Once we randomize the Identification, attacker has a 1/65536 chance of guessing it correctly.
Are we pretty much safe?

Attacker can send lots of replies, not just one …

However: once reply from legit server arrives (with correct Identification), it's **cached** and no more opportunity to poison it. Victim is innoculated!



Unless attacker can send 1000s of replies before legit arrives, we're likely safe – phew! **?**

Enter Kaminski...
Glue Attacks

- Dan Kaminski noticed something strange, however...
  - Most DNS servers would *cache* the in-bailiwick glue...
  - And then ***promote*** the glue
  - And will also ***update*** entries based on glue
- So if you first did this lookup...
  - And then went to **`a0.org.afilias-nst.info`**
  - there would be no other lookup!

```
nweaver% dig +norecurse slashdot.org @a.root-servers.net

; <<>> DiG 9.8.3-P1 <<>> +norecurse slashdot.org @a.root-servers.net
;; global options: +cmd
;; Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 26444
;; flags: qr; QUERY: 1, ANSWER: 0, AUTHORITY: 6, ADDITIONAL: 12

;; QUESTION SECTION:
;slashdot.org.                  IN      A

;; AUTHORITY SECTION:
org.                    172800  IN      NS      a0.org.afilias-nst.info

;; MSG SIZE  rcvd: 432
```

The Kaminski Attack In Practice

- Rather than trying to poison **`www.google.com`**...
- Instead try to poison **`a.google.com`**...
  And state that "**`www.google.com`**" is an authority
  And state that "**`www.google.com A 133.7.133.7`**"
  - If you succeed, great!
- But if you fail, just try again with b.google.com!
  - Turns "Race once per timeout" to "race until win"
- So now the attacker may still have to send lots of packets
  - In the 10s of thousands
- The attacker can keep trying until success

Defending Against Kaminski: Up the Entropy

- Also randomize the UDP source port
  - Adds 16 bits of entropy
- Observe that most DNS servers just copy the request directly
  - Rather than create a new reply
- So caMeLcase the NamE ranDomly
  - Adds only a few bits of entropy however, but it does help

Defend Against Kaminski: Validate Glue

- Don't blindly accept glue records...
  - Well, you ***have*** to accept them for the purposes of resolving a name
- But if you are going to cache the glue record...
- Either only use it for the context of a DNS lookup
  - No more promotion
- Or explicitly validate it with another fetch
- Unbound implemented this, bind did not
  - Largely a ***political*** decision:
    bind's developers are heavily committed to DNSSEC (next week's topic)

Oh, and Profiting from Rogue DNS

- Suppose you take over a lot of h
  - How do you make money with it?
- Simple: Change their DNS server
  - Make it point to yours instead of the ISPs
- Now redirect all advertising
  - And instead serve up ads for "Vimax" pills
