Network Security 8: DNSSEC

Former special representative for Ukraine Kurt Volker testified that he texted from his personal phone because he couldn't figure out how to get into his government phone.

"The password on the government phone always seemed to drop, and I couldn't get into it," he said

News of the Day

Computer Science 161 Fall 2019

GOING BLACK -

Breaking the law: How 8chan (or "8kun") got (briefly) back online

Russian "bulletproof" host advertised stolen IP address to take site live.

SEAN GALLAGHER - 11/5/2019, 3:00 PM

Enlarge / Snek goes dark.

The successor to 8chan, 8kun, made a somewhat brief appearance on the public Internet thanks to what amounts to an attack on the Internet's routing infrastructure. The site's domain name server, hosted by a service called VanwaNet, offered up an Internet address for the site that was from an unallocated set of addresses belonging to the RIPE Network Coordinating Centre, the regional Internet registry authority for Europe and the Middle East. And the host for the new site, the Russian hosting company Media Land LLC, advertised a route to that address to the rest of the Internet, allowing visitors to reach the site for a while.

A Warning: I'm Giving *Unfiltered* DNSSEC

Computer Science 161 Fall 2019

247

Why?

- Because it is a well thought through cryptographic protocol designed to solve a real world data integrity problem
- It is a real world PKI (Public Key Infrastructure) with some very unique trust properties:
 - A constrained path of trust along established business relationships.
- It is important to appreciate the real world of what it takes to build a secure system
- I've worked with it for far too much for my own sanity...
- And I'm a cruel bastard

Hypothetical: Securing DNS Using SSL/TLS

root DNS server ('.') Host at xyz.poly.edu wants parent for .edu IP address for www.mit.edu TLD DNS server ('.edu') parent for mit.edu local DNS server (resolver) dns.poly.edu Idea: connections {1,8}, {2,3}, {4,5} and {6,7} all run over SSL / TLS authoritative DNS server ns.mit.edu child domain requesting host www.mit.edu xyz.poly.edu

But This Doesn't Work

omputer Science 161 Fall 201

...

- TLS provides channel integrity, but we need data integrity
- TLS in this scheme is not end to end
 - In particular, the recursive resolver is a known adversary:
 - "NXDOMAIN wildcarding": a "helpful" page when you give a typo
 - Malicious MitM of targeted schemes for profit
- TLS in this scheme is painfully slow:
 - DNS lookups are 1 RTT, this is 3 RTTs!
- And confidentiality is of little benefit:
 - We use DNS to contact hosts:
 Keeping the DNS secret doesn't actually disguise who you talk to!

DNS security: If the Attacker sees the traffic...

omputer Science 161 Fall 2019

Weave

- All bets are off:
 - DNS offers NO protection against an on-path or in-path adversary
 - Attacker sees the request, sends the reply, and the reply is accepted!
- The recursive resolver is the most common in-path adversary!
 - It is implicitly trusted
 - Yet often abuses the trust
- And this scheme keeps the resolver as the in-path adversary

So Instead Let's Make DNS a PKI and records certificates

omputer Science 161 Fall 2019

- www.berkeley.edu is already trusting the DNS authorities for berkeley.edu, .edu, and . (the root)
 - Since www.berkeley.edu is in bailiwick for all these servers and you end up having to contact all of them to get an answer.
- So let's start signing things:
 - will sign .edu's key
 - .edu will sign Berkeley's key
 - Berkeley's key will sign the record
- DNSSEC: DNS Security Extensions
 - A heirarchical, distributed trust system to validate the mappings of names to values

Enter DNSSEC (DNS Security Extensions)

omputer Science 161 Fall 2019

Meaus

- An extension to the DNS protocol to enable cryptographic authentication of DNS records
 - Designed to prove the value of an answer, or that there is no answer!
 - A restricted path of trust
 - Unlike the HTTPS CA (Certificate Authority) system where your browser trusts every CA to speak for every site
- With backwards compatibility:
 - Authority servers don't need to support DNSSEC
 - But clients should know that the domain is not secured
 - Recursive and stub resolvers that don't support DNSSEC must not receive DNSSEC information

Reminder: DNS Message Structure

omputer Science 161 Fall 2019

Meaus

DNS messages:

- A fixed header: Transaction ID, flags, etc...
- 1 question: Asking for a name and type
- 0-N answers: The set of answers
- 0-N authority: ("glue records"): Information about the authority servers and/or ownership of the domain
- 0-N additional: ("glue records"): Information about the authority server's IP addresses
 - Glue records are needed for the resolution process but aren't the answer to the question

Reminder: DNS Resource Records and RRSETs

omputer Science 161 Fall 2019

Weave

- DNS records (Resource Records) can be one of various types
 - Name TYPE TTL Value
- Groups of records of the same name and type form RRSETs:
 - E.g. all the nameservers for a given domain.
 - All the records in the RRSET have the same name, type, and TTL

The First New Type: OPT

omputer Science 161 Fall 2019

Weaver

- DNS contains some old limits:
 - Only 8 total flag bits, and messages are limited to 512B
- DNSSEC messages are much bigger
- DNSSEC needs two additional flags
 - DO: Want DNSSEC information
 - CD: Don't check DNSSEC information
- EDNS0 (Extension Mechanisms for DNS) adds the OPT resource record
 - Sent in the *request* and reply in the additional section
 - Uses CLASS field to specify how large a UDP reply can be handled
 - Uses TTL field to add 16 flag bits
 - Only flag bit currently used is DO
 - Used to signal to the authority that the client desires DNSSEC information

EDNS0 in action

Computer Science 161 Fall 2019

A query using dig +bufsize=1024 uses EDNS0

```
nweaver% dig +norecurse +bufsize=1024 slashdot.org @a.root-servers.net
; <<>> DiG 9.8.3-P1 <<>> +bufsize=1024 slashdot.org @a.root-servers.net
;; global options: +cmd
:: Got answer:
;; ->>HEADER<<- opcode: QUERY, status: NOERROR, id: 13419
;; flags: qr; QUERY: 1, ANSWER: 0, AUTHORITY: 6, ADDITIONAL: 13
:: OPT PSEUDOSECTION:
; EDNS: version: 0, flags:; udp: 4096
;; QUESTION SECTION:
;slashdot.org.
                                         A
                                 IN
;; AUTHORITY SECTION:
                        172800
                                                 a0.org.afilias-nst.info.
                                IN
                                         NS
org.
```

The second new type, a certificate: RRSIG

omputer Science 161 Fall 2019

Meaus

- A signature over an RRSET (not just a single answer):
 Multiple fields
 - Type: The DNS type which this is the RRSIG for
 - Algorithm: IANA assigned identifier telling the encryption algorithm
 - Labels: Number of segments in the DNS name
 - Original TTL: The TTL for the record delivered by the authority
 - Signature Expiration
 - Signature Inception
 - Both in seconds since January 1, 1970
 - Key tag: What key was used (roughly. Its a checksum on the key bits)
 - Signer's name
 - Signature

So an RRSIG in action (The NS entries for isc.org.)

- Type of the record its an RRSIG for
- Algorithm #5: RSA/SHA-1
- 2 labels in the name
- 7200s initial TTL

nweaver% dig +dnssec NS isc.org @8.8.8.8

- Valid 2013-04-15-23:32:55 to 2013-05-15-23:32:53
- Key tag 50012
- Key belongs to isc.org.
- And lots of cryptogarbage...

How Do We Know What Key To Use Part 1: **DNSKEY**

omputer Science 161 Fall 2019

Weeve

- The **DNSKEY** record stores key information
 - 16 bits of flags
 - Protocol identifier (always 3)
 - Algorithm identifier
 - And then the key itself
- The keys are split into multiple roles
 - The Key Signing Key (KSK) is used only to sign the **DNSKEY** RRSET
 - The Zone Signing Key (ZSK) is used to sign everything else
- The client has hardwired in one key for .
 - This is the root's KSK (Key Signing Key)

The **DNSKEY** for .

Computer Science 161 Fall 2019

- The first is the root's ZSK
- The second is the root's KSK

- The RRSIG is signed using the KSK
 - Now the client can verify that the ZSK is correct

```
nweaver% dig +norecurse +dnssec DNSKEY . @a.root-servers.net

```

But how do we know what key to use part 2? **DS**

omputer Science 161 Fall 2019

Meaus

- The DS (Delegated Signer) record is relatively simple
 - The key tag
 - The algorithm identifier
 - The hash function used
 - The hash of the signer's name and the KSK
- The parent signs DS (Delegated Signer) records for the child's keys
 - So for the DS for .org is provided by the root
 - This is returned with the NS RRSET by the parent
 - And the RRSIG is signed by the parent, not the child

The DS for org.

Computer Science 161 Fall 2019

Means

- The two DS records are for the same key
 - Just with different hash functions, SHA-256 and SHA-1
- The RRSIG is signed using the ZSK not the KSK
 - And covers both DS records

```

And so on...

omputer Science 161 Fall 2019

14/-----

- The process ends up requiring:
 - Ask the root for www.isc.org and the DNSKEY for .
 - Ask org for www.isc.org and the DNSKEY for org.
 - Ask isc.org for www.isc.org and the DNSKEY for isc.org
- Dig commands
 - dig +dnssec +norecurse www.isc.org @a.root-servers.net
 - dig +dnssec +norecurse DNSKEY . @a.root-servers.net
 - dig +dnssec +norecurse www.isc.org @199.19.56.1
 - dig +dnssec +norecurse DNSKEY org. @199.19.56.1
 - dig +dnssec +norecurse www.isc.org @149.20.64.3
 - dig +dnssec +norecurse DNSKEY isc.org. @149.20.64.3

So why such a baroque structure?

Computer Science 161 Fall 2019 We

- Goal is end-to-end data integrity
 - Even authorized intermediaries such as the recursive resolver don't need to be trusted
- Don't benefit (much) from confidentiality since DNS is used to contact hosts
- Signature generation can be done all offline
 - Attacker must compromise the signature generation system, not just the authority nameserver
 - Allows other authority servers to be simply mirrors
- Validation can happen at either the recursive resolver or the client
 - The DNSKEYs cache very well
 - So most subsequent lookups will not need to do these lookups
- Constrained path of trust
 - For a given name, can enumerate the trusted entities

Another reason: Latency

omputer Science 161 Fall 2019

Weaver

- The DNS community is obsessed with latency
 - Thus the refusal to simply switch to TCP for all DNS traffic
- A recursive resolver may
 - Automatically fetch the DNSKEY record with a parallel request
 - While waiting for a child's response, validate the parent's Ds record
 - Generally the validation should be the same time or faster so we can do this in parallel
 - Result: Only two signature validations of latency added even on uncached requests and no additional network latency
 - One for the DNSKEY to get the ZSK
 - One for the final RRSET
- A stub resolver looking up foo.example.com:
 - In parallel fetch Ds and DNSKEY for foo.example.com, example.com, .com, and the DNSKEY for .

Two additional complications

Computer Science 161 Fall 2019

• NOERROR:

The name exists but there is no record of that given type for that name

- For DNSSEC, prove that there is no ds record
 - Says the subdomain doesn't sign with DNSSEC

NXDOMAIN:

- The name does not exist
- NSEC (Provable denial of existence), a record with just two fields
 - Next domain name
 - The next valid name in the domain
 - Valid types for this name
 - In a bitmap for efficiency

NSEC in action

Computer Science 161 Fall 2019

Weens

- Name is valid so NOERROR but no answers
- Single NSEC record for www.isc.org:
 - No names exist between www.isc.org and www-dev.isc.org
 - www.isc.org only has an A, AAAA, RRSIG, and NSEC record

```
nweaver% dig +dnssec TXT www.isc.org @8.8.8.8

```

The Use of NSEC

omputer Science 161 Fall 2019

- Proof that a name exists but no type exists for that name
 - Critical for "This subdomain doesn't support DNSSEC":
 Return an NSEC record with the authority stating "There is no DS record"
- Proof that a name does not exist
 - It falls between the two NSEC names
 - Plus an NSEC saying "there is no wildcard"
 - Provable Denial of Existence
- Allows trivial domain enumeration
 - Attacker just starts at the beginning and walks through the NSEC records
 - Some consider this bad...

So NSEC3

omputer Science 161 Fall 2019

Rather than having the name, use a *hash* of the name

- Hash Algorithm
- Flags

- Iterations of the hash algorithm
- Salt (optional)
- The next name
- The RRTYPEs for this name
 - Otherwise acts like **NSEC**, just in a different space

Comments on NSEC3

omputer Science 161 Fall 2019

Weeve

- It doesn't really prevent enumeration
 - You get a hash-space enumeration instead, but since people chose reasonable names...
 - An attacker can just do a brute-force attack to find out what names exist and don't exist after enumerating the hash space
- The salt is pointless!
 - Since the **whole** name is hashed, **foo.example.com** and **foo.example.org** will have different hashes anyway
- The only way to really prevent enumeration is to dynamically sign values
 - But that defeats the purpose of DNSSEC's offline signature generation

So what can *possibly* go wrong?

omputer Science 161 Fall 2019

- Screwups on the authority side...
 - Too many ways to count...
 - But comcast is keeping track of it: Follow @comcastdns on twitter
- The validator can't access DNSSEC records
- The validator can't process DNSSEC records correctly

Authority Side Screwups...

omputer Science 161 Fall 2019

- Its quite common to screw up
- Tell your registrar you support DNSSEC when you don't
 - Took down HBO Go's launch for Comcast users and those using Google Public DNS
- Rotate your key but present old signatures
- Forget that your signatures expire

And The Recursive Resolver Must Not Be Trusted!

omputer Science 161 Fall 2019

- Most deployments validate at the recursive resolver, not the client
 - Notably Google Public DNS and Comcast
- This provides very little practical security:
 - The recursive resolver has proven to be the biggest threat in DNS
 - And this doesn't protect you between the recursive resolver and your system
- But causes a lot of headaches
 - Comcast or Google invariably get blamed when a zone screws up
 - Fortunately this is getting less common...

DNSSEC transport

omputer Science 161 Fall 2019

Meaus

- A validating client must be able to fetch the DNSSEC related records
 - It may be through the recursive resolver
 - It may be by contacting arbitrary DNS servers on the Internet
- One of these two must work or the client can not validate DNSSEC
 - This acts to limit DNSSEC's real use:
 Signing other types such as cryptographic fingerprints (e.g. DANE)

Probe the Root To Check For DNSSEC Transport

omputer Science 161 Fall 2019

Weave

- Can the client get DNSSEC data from the Internet?
 - Probe every root with DO for:
 - DS for .com with RRSIG
 - DNSKFY for . with RRSIG
 - NSEC for an invalid TLD with RRSIG
- Serves two purposes:
 - Some networks have one or more bad root mirrors
 - Notably one Chinese educational network has root mirrors for all but 3 that don't support DNSSEC
 - If no information can be retrieved
 - Proxy which strips out DNSSEC information and/or can't handle DO

DNSSEC Root Transport: Results We've Seen In The Wild

omputer Science 161 Fall 2019

Moovo

- Bad news at Starbucks: Hotspot gateways often proxy all DNS and can't handle DO-enabled traffic
- And then have DNS resolvers that can't handle DNSSEC requests!
- Confirmed the Chinese educational network "Bad root mirror" problem happened
 - China had local root mirrors that didn't implement DNSSEC a few years back

Implications of "No DNSSEC at Starbucks"

omputer Science 161 Fall 2019

Meau

- DNSSEC failure depends on the usage.
- For name->address bindings:
 - If the recursive resolver practices proper port randomization:
 - No problem. The same "attackers" who can manipulate your DNS could do anything they
 want at the proxy that's controlling your DNS traffic
 - Else:
 - Problem. Network is not secure
- For name->key bindings:
 - Unless the resolver supports it directly, you are Out of Luck
 - DNSSEC information must have an alternate channel if you want to use it to transmit keys instead of just IPs

In fact, my preferred DNSSEC policy For Client Validation

omputer Science 161 Fall 2019

Meau

- For name->address mappings
 - Any existing APIs that don't provide DNSSEC status
 - If valid: use
 - If invalid OR no complete DNSSEC chain:
 - Begin an iterative fetch with the most precise DNSSEC-validated data
 - Use the result without question
- For name->data mappings
 - An API which returns DNSSEC status
 - If valid: Use
 - If invalid: Return DNSSEC failure status
 - Up to the application

And That's The Real Thing...

omputer Science 161 Fall 2019

Moovo

- DNSSEC in all its *emm* glory.
- OPT records to say "I want DNSSEC"
- RRSIG records are certificates
- DNSKEY records hold public keys
- DS records hold key fingerprints
 - Used by the parent to tell the child's keys
- NSEC/NSEC3 records to prove that a name doesn't exist or there is no record of that type
